.

Dr. Saeed Alghamdi, Statistics Department, Faculty of Sciences, King Abdulaziz University

Objectives

- Test a distribution for goodness of fit using chisquare.
- Test two variables for independence using chisquare.
- Test proportions for homogeneity using chisquare.

Dr. Saeed Alghamdi, Statistics Department, Faculty of Sciences, King Abdulaziz University

Notes

Introduction

- The chi-square distribution can be used for tests concerning frequency distributions, such as: "If a sample of buyers is given a choice of automobile colors, will each color be selected with the same frequency?"
- The chi-square distribution can also be used to test the independence of two variables. For example, "Are senators' opinions on gun control independent of party affiliations?"
- The chi-squared distribution can be used to test the homogeneity of proportions. For example: "Is the proportion of high school seniors who attend college immediately after graduating the same for the northern, southern, eastern, and western parts of the United States?"

Dr. Saeed Alghamdi, Statistics Department, Faculty of Sciences, King Abdulaziz University

Notes

-

Dr. Saeed Alehamdi, Statistics Department, Faculty of Sciences, Kine Abdulaziz University 11.8

Test for Goodness-of-Fit

- The chi-square statistic can be used to see whether a frequency distribution fits a specific pattern.
- The formula for the chi-square goodness-of-fit test:

$$X^2 = \sum \frac{(O-E)^2}{E}$$

with d.f.= number of categories - 1

O = observed frequency

E = expected frequency

- This test is a right-tailed test, since when the (O E) values are squared, the answer will be positive or zero.
- The assumptions includes that the data must be obtained from a random sample and the expected frequency for each category must be 5 or more.

Dr. Saeed Alghamdi, Statistics Department, Faculty of Sciences, King Abdulaziz University

Test for Goodness-of-Fit

 A Good Fit: When the observed values and expected values are close together, the chi-square test value will be small. Then the decision will be not to reject the null-hypothesis—hence, there is a "good fit."

 Not A Good Fit: When the observed values and the expected values are far apart, the chi-square test value will be large. Then, the null hypothesis will be rejected—hence, there is "not a good fit."

"not a good fit."

Dr. Saced Alghamdi, Statistics Department, Faculty of Sciences, King Abdulaziz Univers

Notes

Dr. Sased Alghandi, Statistics Department, Faculty of Sciences, King Abdataziz University

11-12

Chi-Square Goodness-of-Fit Procedure

- Step 1 State the hypotheses and identify the claim.
- Step 2 Find the critical value. The test is always right-tailed.
- Step 3 Compute the test value. Find the sum of the $\frac{(O-E)^2}{E}$ values.
- Step 4 Make the decision.
- Step 5 Summarize the results.

Dr. Saeed Alghamdi, Statistics Department, Faculty of Sciences, King Abdulaziz University

Notes

<u> </u>
.

Dr. Saeed Alghamdi, Statistics Department, Faculty of Sciences, King Abdulaziz University

Goodness-of-Fit Results

- When there is a perfect agreement between the observed and the expected values, $\chi^2 = 0$, but χ^2 can never be negative.
- The test is right-tailed because " H_0 : Good fit" and " H_1 : Not a good fit" means that χ^2 will be small in the first case and χ^2 will be large in the second case.

Dr. Saeed Alghamdi, Statistics Department, Faculty of Sciences, King Abdulaziz University

Independence Test

- The chi-square *independence test* can be used to test the independence of two variables.
- H_0 : There is no relationship between two variables.
- H_1 : There is a relationship between two variables.
- If the null hypothesis is rejected, there is some relationship between the variables.
- In order to test the null hypothesis, one must compute the expected frequencies, assuming the null hypothesis is true.
- When data are arranged in table form for the independence test, the table is called a *contingency* table.

11-24

Independence Test

• The formula for the test value for the independence test is the same as the one for the goodness-of-fit test.

$$\chi^2 = \sum \frac{(O - E)^2}{E}$$

with d.f. = (R - 1)(C - 1) O = observed frequency E = expected frequency

Dr. Saeed Alghamdi, Statistics Department, Faculty of Sciences, King Abdulaziz University

Homogeneity of Proportions Test

- Homogeneity of proportions test is used when samples are selected from several different populations and the researcher is interested in determining whether the proportions of elements that have a common characteristic are the same for each population.
- H_0 : $p_1 = p_2 = p_3 = ... = p_n$.
- H_1 : At least one proportion is different from the others.
- When the null hypothesis is rejected, it can be assumed that the proportions are not all equal.

Dr. Saeed Alghamdi, Statistics Department, Faculty of Sciences, King Abdulaziz University 11-28

Independence and Homogeneity

- The procedures for the chi-square independence and homogeneity tests are identical and summarized below.
- \bullet $\,$ Step 1 $\,$ State the hypotheses and identify the claim.
- Step 2 Find the critical value in the right tail.
- Step 3 Compute the test value. To compute the test value, first find the expected values. For each cell of the contingency table, use the formula

 $E = \frac{\text{(row sum)(column sum)}}{\text{grand total}}$

to get the expected value. To find the test value, use the formula $\chi^2 = \sum \frac{(O-E)^2}{2}$

• Step 4 Make the decision and Summarize the results.

Dr. Saeed Alghamdi, Statistics Department, Faculty of Sciences, King Abdulaziz University

Notes

Assumptions

- The assumptions for the chi-square independence and homogeneity tests:
 - 1. The data are obtained from a random sample.
 - 2. The expected value in each cell must be 5 or more.

Dr. Saced Alabamdi Statistics Department Faculty of Sciences. King Abdulaviz University

Dr. Saeed Alghamdl, Statistics Department, Faculty of Sciences, King Abdulaziz University 11-32

A sociology wishes to see whether the number of years of college a person has completed is related to her or his place of residence. A sample of 88 people is selected and classified as shown.

| No. | Four years | Advanced | A

Location	No college	Four-year degree	Advanced degree	Total
Urban	15 <u>(11.53)</u>	12 (13.92)	8 <u>(9.55)</u>	35
Suburban	8 <u>(10.55)</u>	15 <u>(12.73)</u>	9 <u>(8.73)</u>	32
Rural	6 <u>(6.92)</u>	8 <u>(8.35)</u>	7 <u>(5.73)</u>	21
Total	29	35	24	88

11-33

- At α = 0.05, can the sociologist conclude that a person's location is dependent on the number of years of college?

 H_0 : A person's place of residence is independent of the number of years of college completed.

 H_1 : A person's place of residence is dependent on the number of years of college completed.

• The degrees of freedom are (3-1)(3-1)=4, hence the critical value is 9.488.

$$\chi^{2} = \sum \frac{(O - E)^{2}}{E} = \frac{(15 - 11.53)^{2}}{11.53} + \frac{(13 - 13.92)^{2}}{13.92} + \frac{(8 - 9.55)^{2}}{9.55} + \frac{(8 - 10.55)^{2}}{10.55} + \frac{(15 - 12.73)^{2}}{12.73} + \frac{(9 - 8.73)^{2}}{8.73} + \frac{(6 - 6.92)^{2}}{6.92} + \frac{(8 - 8.35)^{2}}{8.35} + \frac{(7 - 5.73)^{2}}{5.73} = 3.01$$

• Since 3.01 < 9.488, the decision is not to reject the null hypothesis.

Dr. Saeed Alghamdi, Statistics Department, Faculty of Sciences, King Abdulaziz University

A researcher selected a sample of 50 seniors from each of three area high schools and asked each senior, "Do you drive to school in a car owned by either you or you parents?" The data are shown in the table. At $\alpha=0.05$, test the claim that the proportion of students who drive their own or their parents' car is the same at all three schools.

	School 1	School 2	School 3	Total
Yes	18	22	16	56
No	32	28	34	94
Total	50	50	50	150

State the hypotheses

 H_0 : $p_1=p_2=p_3$ H_1 : At least one proportion is different from the others.

Step 2 Find the critical value. The formula for the degrees of freedom is the same as before: (rows -1)(columns -1) = (2-1)(3-1) = 1(2) = 2. The critical value is 5.991.

Compute the test value. First, compute the expected values.

$$\begin{split} E_{1,1} &= \frac{(56)(50)}{150} = 18.67 & E_{2,1} &= \frac{(94)(50)}{150} = 31.33 \\ E_{1,2} &= \frac{(56)(50)}{150} = 18.67 & E_{2,2} &= \frac{(94)(50)}{150} = 31.33 \\ E_{1,3} &= \frac{(56)(50)}{150} = 18.67 & E_{2,3} &= \frac{(94)(50)}{150} = 31.33 \end{split}$$

 ${\bf Dr.\,Saeed\,Alghamdi,\,Statistics\,Department, Faculty\,of\,Sciences,\,King\,Abdulaziz\,University}$

11-37

11-39

Notes
<u> </u>
11-38 Dr. Saeed Alghamdi, Statistics Department, Faculty of Sciences, King Abdulaziz University

The completed table is shown here.

	School 1	School 2	School 3	Total
Yes	18 (18.67)	22 (18.67)	16 (18.67)	56
No	32 (31.33)	28 (31.33)	34 (31.33)	94
Total	50	50	50	150

$$\begin{split} \chi^2 &= \sum_{E} \frac{(O-E)^2}{E} \\ &= \frac{(18-118.67)^2}{18.67} + \frac{(22-18.67)^2}{18.67} + \frac{(16-18.67)^2}{18.67} \\ &+ \frac{(32-31.33)^2}{31.33} + \frac{(28-31.33)^2}{31.33} + \frac{(34-31.33)^2}{31.33} \\ &= 1.596 \end{split}$$

Step 4 Make the decision. The decision is not to reject the null hypothesis, since 1.596 < 5.991.

Step 5 Summarize the results. There is not enough evidence to reject the null hypothesis that the proportions of high school students who drive their own or their parents' car to school are equal for each school.

Summary

- There are three main uses of the chi-square distribution:
 - The test of independence is used to determine whether two variables are related or are independent.
 - It can be used as goodness-of-fit test, in order to determine whether the frequencies of a distribution are the same as the hypothesized frequencies.
 - 3. The homogeneity of proportions test is used to determine if several proportions are all equal when samples are selected from different populations.
