University Chemistry

# ORGANIC CHEMISTRY

- Organic chemistry is very important branch of chemistry and it study the compounds which contain carbon (C) and hydrogen (H), in general, and may contains other atoms such as oxygen (O), nitrogen (N), sulfur (S),...etc.

## Classification of organic compounds

## •DRAWING ORGANIC MOLECULES

**Molecular formulae:** A molecular formula simply counts the numbers of each sort of atom present in the molecule, but tells you nothing about the way they are joined together.

**Example:**

the molecular formula of butane is  $C_4H_{10}$ , and the molecular formula of ethanol is  $C_2H_6O$ .

**Structural formulae:** A structural formula shows how the various atoms are bonded.

**Example:**

ethanoic acid would be shown in a fully displayed form and a simplified form as:

- **Skeletal formulae:** all the hydrogen atoms are removed from carbon chains, leaving just a carbon skeleton with functional groups attached to it.

- **Example:**

- butan-2-ol

Cyclohexane,  $\text{C}_6\text{H}_{12}$

## STRUCTURAL ISOMERISM:

Isomers are molecules that have the same molecular formula, but have a different arrangement of the atoms in space.

### Types of structural isomerism

**(A) Chain isomerism:** due to possibility of branching in carbon chains.

**Example:**

there are two isomers of butane,  $\text{C}_4\text{H}_{10}$ .

**(B) Position isomerism:** the basic carbon skeleton remains unchanged, but important groups are moved around on that skeleton.

**Example:**

there are two structural isomers with the molecular formula  $C_3H_7Br$ .

**Functional group isomerism**

The isomers contain different functional groups, and they belong to different families of compounds

**Example**

molecular formula  $C_3H_6O$  could be either propanal (an aldehyde) or propanone (a ketone).

# Aliphatic hydrocarbons

- **Alkanes:**

- they are saturated hydrocarbons, because all the carbon atoms are bonded with 4 single covalent bonds.
- **General formula:  $C_nH_{2n+2}$**

## Bonding in Alkanes

So, alkane (four single bonds) have  $sp^3$  hybridization, where four  $sp^3$  orbitals are produced which can form sigma ( $\sigma$ ) bonds, with an angle of  $109^\circ 28'$  between bonds.

- **Nomenclature**: a chemical name has three parts:  
**prefix**, **parent**, and **suffix**
- **prefix**: Tells #, types & where side groups attached
- **parent**: Tells # of Cs in longest continuous chain
- **suffix**: Tells which functional group is present
- Straight chain alkanes are named by counting the number of carbon atoms in the longest chain and adding the **suffix -ane**.

<i>Number of carbon</i>	<i>Compound</i>	<i>Alkane name</i>	<i>Application</i>
1 (Meth)	CH <sub>4</sub>	methane	found in natural gas
2 (Eth)	C <sub>2</sub> H <sub>6</sub>	ethane	used making ethylene
3 (Prop)	C <sub>3</sub> H <sub>8</sub>	propane	heating and barbecues
4 (But)	C <sub>4</sub> H <sub>10</sub>	butane	lighter fluid
5 (Pent)	C <sub>5</sub> H <sub>12</sub>	pentane	Solvent
6 (Hex)	C <sub>6</sub> H <sub>14</sub>	hexane	part of gasoline
7 (Hept)	C <sub>7</sub> H <sub>16</sub>	heptane	part of gasoline
8 (Oct)	C <sub>8</sub> H <sub>18</sub>	octane	
9 (non)	C <sub>9</sub> H <sub>20</sub>	nonane	
10 (dec)	C <sub>10</sub> H <sub>22</sub>	decane	

# How to name open chain compounds?

- To name alkanes and any other organic compounds:

- 1. Find the longest continuous chain of carbon atoms; this is a **hexane** (6 carbon atoms).
- 2. Alkane groups as substituents are named as follows:
  - CH<sub>3</sub> methyl
  - CH<sub>2</sub>CH<sub>3</sub> ethyl
  - CH<sub>2</sub>CH<sub>2</sub>CH<sub>3</sub> propyl
- 3. Number the long chain so that the substituents are at the lowest numbers, and the substituent at carbon number 3.

**The name for this alkane is: 3-ethylhexane**

# Draw the structures for n-butane and isobutene

## n-butane

**n** means normal chain (straight), and but means 4 carbon atoms.

put 4 carbon atoms beside each other and make each one connected to 4 single bonds:

## isobutane

**iso** means branched chain, and but means 4 carbon atoms.

put 3 carbon atoms beside each other and connect the forth C atom to the middle carbon, and make each one connected to 4 single bonds:

# Aliphatic hydrocarbons

- **Alkenes:**

- Alkenes are unsaturated hydrocarbons (contain at least one **C=C** double bond)

- **General formula:  $C_nH_{2n}$**

- **Naming Alkenes:** count the number of the carbon atoms in the longest chain, and add the suffix **-ene** at the end.

ethene (ethylene)

propene (propylene)

butene

1-butene

2-butene

## ***cis-trans* isomerism**

Alkenes have two different geometrical isomerism, *cis* and *trans*.

*cis*-2-butene

*trans*-2-butene

## Bonding in alkene

In alkene (one double bond and two single bonds) have  $sp^2$  hybridization, where three  $sp^2$  orbitals are produced which can form three sigma ( $\sigma$ ) bonds, with an angle of  $120^\circ$  between bonds, and one pi ( $\pi$ ) bond from the pure p orbitals.

# Aliphatic hydrocarbons

- **Alkynes:**
- Alkynes are unsaturated hydrocarbons (contain at least one  $\text{C}\equiv\text{C}$  triple bond)
- **General formula:**  $\text{C}_n\text{H}_{2n-2}$
- **Naming Alkynes:** count the number of the carbon atoms in the longest chain, and add the suffix **-yne** at the end.

## Bonding in alkyne

In alkyne (one triple bond and one single bonds) have  $sp$  hybridization, where two  $sp$  orbitals are produced which can form two sigma ( $\sigma$ ) bonds, with an angle of  $180^\circ$  between bonds, and two pi ( $\pi$ ) bond from the pure  $p$  orbitals.

alkane

alkene

alkyne

phenyl

alkyl halide  
(X = F, Cl, Br, I)

amine

alcohol

ether

aldehyde

ketone

carboxylic  
acid

ester

amide

# Aromatic Hydrocarbons and their Nomenclature

Benzene is the most common aromatic parent structure

The benzene ring is named as a phenyl group when it is a substituent.

Multiple substituent's on a benzene ring:

1,2-dichlorobenzene

ortho *o*-dichlorobenzene

1,3-dichlorobenzene

meta *m*-dichlorobenzene

1,4-dichlorobenzene

para *p*-dichlorobenzene

## Some common names involving benzene rings

**Biphenyl:** involve two benzene rings bonds together and follow the numbering system.

**Polycyclic aromatic hydrocarbons,** which contains fused benzene rings

## Number of bonds

For each single bond count one sigma bond, for each double bond count one sigma bond and one pi bond, and finally for each triple bond count one sigma bond and two pi bonds.

**Name the following compounds and count the total number of bonds:**

The longest chain contains 8 carbons, so it is oct

All single bonds, so it is octane

Ethyl branch at carbon number 4, and methyl branch at carbon number 3, so its name is: 4-ethyl- 3- methyl-octane

Bond: all are single bonds, 34 sigma bonds.

The longest chain contains 5 carbons, so it is pent  
One double bond = at carbon number 2, so it is 2-pentene.

Methyl branch at carbon number 4, so its name is: 4-methyl-2-pentene

Bond: One double bond =, counts as 1 sigma and 1 pi, 16 other single (sigma). 17 sigma and 1 pi bond, so the total number of bonds is 18.

The longest chain contains 8 carbons, so it is oct

One triple bond  $\equiv$  at carbon number 3, so it is 3-octyne.

Methyl branch at carbon number 7, so its name is: 7-methyl-3-octyne

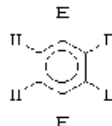

Bond: One triple bond  $\equiv$ , counts as 1 sigma and 2 pi, 23 other single (sigma) bonds. 24 sigma and 2 pi bond, so the total number of bonds is 26.

**It is benzene, with two chloro substitution at position 1, 2.  
Its name is 1,2-dichlorobenzene or ortho- dichlorobenzene.**

**Bond: three double bond =, counts as 1 sigma and 1 pi, 9 other single (sigma) bonds. 12 sigma and 3 pi bond, so the total number of bonds is 15.**

# Biochemistry

- Biochemistry is the chemistry of living organisms.
- It is the application of chemistry to study the different biological processes at the cellular and molecular level.
- In general, Chemistry deals with objects at the *molecular* scale and the fundamental unit of living organisms is the *cell* (macroscopic scale), so, consequently, biochemistry tries to span *both* of these worlds (molecules and cells).

## Basic Structures and Mechanisms

The basic structures of biochemistry are *biomolecules*, which are molecules created by living organisms. There are four main categories of biomolecules:

- 1) Proteins
- 2) Carbohydrates
- 3) Lipids
- 4) Nucleic Acids

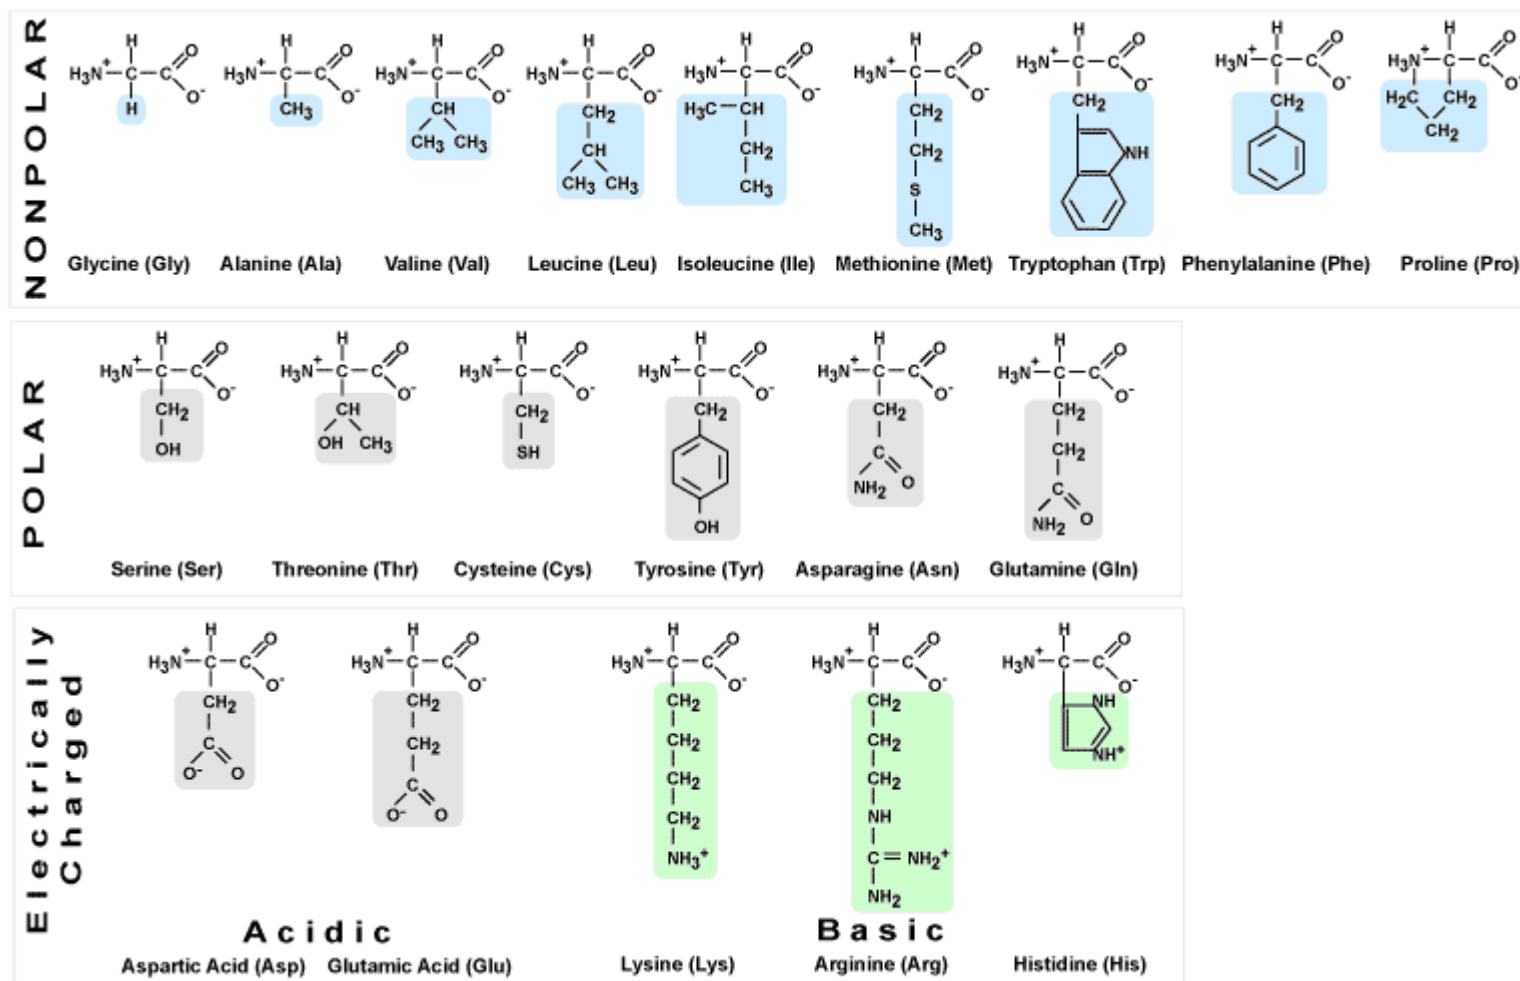

# Proteins

- Proteins are macromolecules made up of amino acids. Amino acids: consist of an amino group, a carboxyl group, a hydrogen atom and a distinctive R group bonded to a carbon atom.

There are twenty different types of side chains (20 amino acids).

- **NUCLEIC ACIDS**

DNA and RNA are used to direct the activity of cells. Cells look and function a certain way because of directions contained in the DNA. They have 3 Parts: a **Carbohydrate** (pentose, a 5 carbon sugar), a single **Base** (one of five possibilities), a **Phosphorous** Here is what they look like all put together.

- Nucleic acids are linked together to form long chains, and DNA is made of ***two parallel*** chains. These parallel chains have a twist to them so DNA is often called a **Double Helix** making the DNA molecules.

Fig. 8.7 DNA structure and the formation of the double Helix.
