Thermo 1 (MEP 261)

*Thermodynamics An Engineering Approach*

Yunus A. Cengel & Michael A. Boles

7th Edition, McGraw-Hill Companies,

**Sheet 8: Chapter 9**

8–2C How does the thermal efficiency of an ideal cycle, in general, compare to that of a Carnot cycle operating between the same temperature limits?

**Solution** It is less than the thermal efficiency of a Carnot cycle.

8–3C What does the area enclosed by the cycle represent on a $P$-$v$ diagram? How about on a $T$-$s$ diagram?

**Solution** It represents the net work on both diagrams.

8–4C What is the difference between air-standard assumptions and the cold-air-standard assumptions?

**Solution** The cold air standard assumptions involve the additional assumption that air can be treated as an ideal gas with constant specific heats at room temperature.

8–5C How are the combustion and exhaust processes modeled under the air-standard assumptions?

**Solution** Under the air standard assumptions, the combustion process is modeled as a heat addition process, and the exhaust process as a heat rejection process.
9–6C What are the air-standard assumptions?

**Solution** The air standard assumptions are: (1) the working fluid is air which behaves as an ideal gas, (2) all the processes are internally reversible, (3) the combustion process is replaced by the heat addition process, and (4) the exhaust process is replaced by the heat rejection process which returns the working fluid to its original state.

9–7C What is the difference between the clearance volume and the displacement volume of reciprocating engines?

**Solution** The clearance volume is the minimum volume formed in the cylinder whereas the displacement volume is the volume displaced by the piston as the piston moves between the top dead center and the bottom dead center.

9–8C Define the compression ratio for reciprocating engines.

**Solution** It is the ratio of the maximum to minimum volumes in the cylinder.

9–9C How is the mean effective pressure for reciprocating engines defined?

**Solution** The MEP is the fictitious pressure which, if acted on the piston during the entire power stroke, would produce the same amount of net work as that produced during the actual cycle.

9–12C What is the difference between spark-ignition and compression-ignition engines?

**Solution** The SI and CI engines differ from each other in the way combustion is initiated: by a spark in SI engines, and by compressing the air above the self-ignition temperature of the fuel in CI engines.

9–13C Define the following terms related to reciprocating engines: stroke, bore, top dead center, and clearance volume.

**Solution** Stroke is the distance between the TDC and the BDC, bore is the diameter of the cylinder, TDC is the position of the piston when it forms the smallest volume in the cylinder, and clearance volume is the minimum volume formed in the cylinder.
9–14 An air-standard cycle with variable specific heats is executed in a closed system and is composed of the following four processes:
1-2 Isentropic compression from 100 kPa and 27°C to 800 kPa
2-3 $v = \text{constant}$ heat addition to 1800 K
3-4 Isentropic expansion to 100 kPa
4-1 $P = \text{constant}$ heat rejection to initial state

(a) Show the cycle on $P-v$ and $T-s$ diagrams.
(b) Calculate the net work output per unit mass.
(c) Determine the thermal efficiency.

**Solution** The four processes of an air-standard cycle are described. The cycle is to be shown on $P-v$ and $T-s$ diagrams, and the net work output and the thermal efficiency are to be determined.

**Assumptions**

1. The air-standard assumptions are applicable.
2. Kinetic and potential energy changes are negligible.
3. Air is an ideal gas with variable specific heats.

**Properties** The properties of air are given in Table A-17.

**Analysis (b)** The properties of air at various states are

1-2: Isentropic compression from 100 kPa and 27°C to 800 kPa
$p_1 = 100$ kPa, $T_1 = 27 + 273 = 300$ K, $p_2 = 800$ kPa,
For air, From Table A-17,
For $T_1 = 300$ K, $h_1 = 300.19$ kJ/kg,
$T_2p_2^{(1-k)/k} = T_1p_1^{(1-k)/k}$,
$T_2 = T_1 [p_1/p_2]^{1-1.4/1.4}$, $T_2 = 300 [100/800]^{1-1.4/1.4} = 543.43$ K
Hence, from Table A-17, for $T_2 = 543.43$ K, $u_2$ is obtained by interpolation for $u$ corresponding to $T = 540$ K and 550 K.

<table>
<thead>
<tr>
<th>T(K)</th>
<th>$u$ (KJ/kg)</th>
</tr>
</thead>
<tbody>
<tr>
<td>540</td>
<td>389.34</td>
</tr>
<tr>
<td>543.43</td>
<td>$u$</td>
</tr>
<tr>
<td>550</td>
<td>396.86</td>
</tr>
</tbody>
</table>
\[(u_2 - 389.34)/(396.86 - 389.34) = (543.43 - 540)/(550 - 540)\]
\[u_2 = 391.92 \text{ KJ/kg}\]

2-3: \(v = \text{constant}\) heat addition to 1800 K

\[T_3 = 1800 K\]

Hence, from Table A-17, for \(T_3 = 1800 K\), \(u_4 = 1487.2 \text{ KJ/kg}\)
\[P_3 \sqrt{T_3} = P_2 \sqrt{T_2},\]

Hence,
\[P_3/T_3 = P_2/T_2, P_3/T_3\]

\[Hence, P_3 = P_2 \left( T_3/T_2 \right) = 800 \left(1800/543.43\right) = 2649.83 \text{ KPa}\]

3-4: Isentropic expansion from 2649.83 KPa & 1800 K to 100 kPa

\[T_4 = T_3 \left[ p_3/p_4 \right]^{\left(1-1.4\right)/1.4}, T_4 = 1800 \left[2649.83/100\right]^{\left(1-1.4\right)/1.4} = 705.73 K\]

Hence, from Table A-17, for \(T_4 = 705.73 K\), \(h_4\) is obtained by interpolation for \(h\) corresponding to \(T = 700 K\) and 710 K.

<table>
<thead>
<tr>
<th>T(K)</th>
<th>h (KJ/kg)</th>
</tr>
</thead>
<tbody>
<tr>
<td>700</td>
<td>713.27</td>
</tr>
<tr>
<td>705.73</td>
<td>h</td>
</tr>
<tr>
<td>710</td>
<td>724.04</td>
</tr>
</tbody>
</table>

\[(h_4 - 713.27)/(724.04 - 713.27) = (705.73 - 700)/(710 - 700)\]
\[h_4 = 719.44 \text{ KJ/kg}\]

From energy balances,
\[q_{in} = u_3 - u_2 = 1487.2 \text{ KJ/kg} - 391.92 \text{ KJ/kg} = 1095.28 \text{ KJ/kg}\]
\[q_{out} = h_4 - h_1 = 719.44 \text{ KJ/kg} - 300.19 \text{ kJ/kg} = 419.25 \text{ KJ/kg}\]
\[w_{net} = q_{in} - q_{out} = 1095.28 \text{ KJ/kg} - 419.25 \text{ KJ/kg} = 676.03 \text{ KJ/kg}\]

The thermal efficiency is,
\[\eta_{th} = w_{net}/q_{in} = 676.03 / 1095.28 = 0.6172 * 100\% = 61.72 \%\]
An air-standard cycle is executed in a closed system and is composed of the following four processes:

1-2 Isentropic compression from 100 kPa and 27°C to 1 MPa
2-3 \( P = \text{constant} \) heat addition in amount of 2800 kJ/kg
3-4 \( v = \text{constant} \) heat rejection to 100 kPa
4-1 \( P = \text{constant} \) heat rejection to initial state

(a) Show the cycle on \( P-v \) and \( T-s \) diagrams.
(b) Calculate the maximum temperature in the cycle.
(c) Determine the thermal efficiency.

Assume constant specific heats at room temperature.

**Answers:** (b) 3360 K, (c) 21.0 percent

**Solution** The four processes of an air-standard cycle are described. The cycle is to be shown on \( P-v \) and \( T-s \) diagrams, and the maximum temperature in the cycle and the thermal efficiency are to be determined.

**Assumptions**
1. The air-standard assumptions are applicable.
2. Kinetic and potential energy changes are negligible.
3. Air is an ideal gas with constant specific heats.

**Properties** The properties of air at room temperature are \( c_p = 1.005 \) kJ/kg·K, \( c_v = 0.718 \) kJ/kg·K, and \( k = 1.4 \) (Table A-2).

**Analysis** (b) From the ideal gas isentropic relations and energy balance,
\[ T_2 = T_1 \left( \frac{P_2}{P_1} \right)^{(k-1)/k} = (300 \text{ K}) \left( \frac{1000 \text{ kPa}}{100 \text{ kPa}} \right)^{0.4/1.4} = 579.2 \text{ K} \]

\[ q_{\text{in}} = h_3 - h_2 = c_p (T_3 - T_2) \]

\[ 2800 \text{ kJ/kg} = (1.005 \text{ kJ/kg} \cdot \text{K})(T_3 - 579.2) \rightarrow T_{\text{max}} = T_3 = 3360 \text{ K} \]

(c) \[ \frac{P_3 v_3}{T_3} = \frac{P_4 v_4}{T_4} \rightarrow T_4 = \frac{P_4}{P_3} T_3 = \frac{100 \text{ kPa}}{1000 \text{ kPa}} (3360 \text{ K}) = 336 \text{ K} \]

\[ q_{\text{out}} = q_{34,\text{out}} + q_{41,\text{out}} = (u_3 - u_4) + (h_4 - h_1) \]

\[ = c_v (T_3 - T_4) + c_p (T_4 - T_1) \]

\[ = (0.718 \text{ kJ/kg} \cdot \text{K})(3360 - 336)\text{K} + (1.005 \text{ kJ/kg} \cdot \text{K})(336 - 300)\text{K} \]

\[ = 2212 \text{ kJ/kg} \]

\[ \eta_{th} = [1 - (q_{\text{out}}/q_{\text{out}})] \times 100\% = [1 - (2212 \text{ kJ/kg}/(2800 \text{ kJ/kg}))] \times 100\% = 21.0\% \]

**Discussion** The assumption of constant specific heats at room temperature is not realistic in this case as the temperature changes involved are too large.

---

9–20 An air-standard cycle with variable specific heats is executed in a closed system with 0.003 kg of air and consists of the following three processes:

1-2 \( \nu = \text{constant} \) heat addition from 95 kPa and 17°C to 380 kPa

2-3 Isentropic expansion to 95 kPa

3-1 \( P = \text{constant} \) heat rejection to initial state

(a) Show the cycle on \( P-\nu \) and \( T-s \) diagrams.

(b) Calculate the net work per cycle, in kJ.

(c) Determine the thermal efficiency.
2-3 Isentropic expansion to 95 kPa.

\[ P_3 = 95 \text{ kPa} \]

\[ T P^{(1-k)/k} = C, \]

Hence,

\[ T_3 P_3^{(1-k)/k} = T_2 P_2^{(1-k)/k} \]

\[ T_3 = T_2 \left( \frac{P_2}{P_3} \right)^{(1-k)/k} \]

Hence, \[ T_3 = 1160 \text{ K} \left( \frac{380 \text{ kPa}}{95 \text{ kPa}} \right)^{(1-1.4)/1.4} \]

i.e., \[ T_3 = 780.622 \text{ K} \]

From Table A-17, \[ h_3 = 800.03 \text{ kJ/kg} \]

\[ Q_{in} = m \left( u_2 - u_1 \right) = 0.003 \text{ kg} \times \left( 897.91 - 206.91 \right) \text{ kJ/kg} = 2.073 \text{ kJ} \]

\[ Q_{out} = m \left( h_2 - h_1 \right) = 0.003 \text{ kg} \times \left( 800.03 - 290.16 \right) \text{ kJ/kg} = 1.5296 \text{ kJ} \]

\[ W_{net,out} = 2.073 \text{ kJ} - 1.5296 \text{ kJ} = 0.5434 \text{ kJ} \]

\[ \eta_{th} = \frac{W_{net,out}}{Q_{in}} = \frac{0.5434}{2.073} \times 100\% = 26.21\% \]
9–21 Repeat Problem 9–20 using constant specific heats at room temperature.

**Solution** The three processes of an air-standard cycle are described. The cycle is to be shown on $P$-$\nu$ and $T$-$s$ diagrams, and the net work per cycle and the thermal efficiency are to be determined.

**Assumptions** 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with constant specific heats.

**Properties** The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg·K}$, $c_v = 0.718 \text{ kJ/kg·K}$, and $\lambda = 1.4$ (Table A-2).

**Analysis (b)** From the isentropic relations and energy balance,

$$
\frac{P_2 \nu_2}{T_2} = \frac{P_1 \nu_1}{T_1} \rightarrow T_2 = \frac{P_2}{P_1} T_1 = \frac{380 \text{ kPa}}{95 \text{ kPa}} (290 \text{ K}) = 1160 \text{ K}
$$

$$
T_3 = T_2 \left( \frac{P_3}{P_2} \right)^{(k-1)/k} = (1160 \text{ K}) \left( \frac{95 \text{ kPa}}{380 \text{ kPa}} \right)^{0.4/1.4} = 780.6 \text{ K}
$$

$$
Q_{\text{in}} = m(\nu_2 - \nu_1) = mc_v (T_2 - T_1) = (0.003 \text{ kg})(0.718 \text{ kJ/kg·K})(1160 - 290)\text{K} = 1.87 \text{ kJ}
$$

$$
Q_{\text{out}} = m(h_3 - h_1) = mc_p (T_3 - T_1) = (0.003 \text{ kg})(1.005 \text{ kJ/kg·K})(780.6 - 290)\text{K} = 1.48 \text{ kJ}
$$

$$
W_{\text{net, out}} = Q_{\text{in}} - Q_{\text{out}} = 1.87 - 1.48 = 0.39 \text{ kJ}
$$

(c) $$
\eta_{\text{in}} = \frac{W_{\text{net}}}{Q_{\text{in}}} = \frac{0.39\text{kJ}}{1.87\text{kJ}} = 20.9\%
$$

9–22 Consider a Carnot cycle executed in a closed system with 0.003 kg of air. The temperature limits of the cycle are 300 and 900 K, and the minimum and maximum pressures that occur during the cycle are 20 and 2000 kPa. Assuming constant specific heats, determine the net work output per cycle.
Solution  A Carnot cycle with the specified temperature limits is considered. The net work output per cycle is to be determined.

Assumption  Air is an ideal gas with constant specific heats.

Properties  The properties of air at room temperature are \(c_p = 1.005 \text{ kJ/kg} \cdot \text{K} \), \(c_v = 0.718 \text{ kJ/kg} \cdot \text{K} \), \(R = 0.287 \text{ kJ/kg} \cdot \text{K} \), and \(k = 1.4 \) (Table A-2).

Analysis  The minimum pressure in the cycle is \(P_3\) and the maximum pressure is \(P_1\). Then,

\[
\frac{T_2}{T_3} = \left( \frac{P_2}{P_3} \right)^{k/(k-1)}
\]

or,

\[
P_2 = P_3 \left( \frac{T_2}{T_3} \right)^{k/(k-1)} = (20 \text{ kPa}) \left( \frac{900 \text{ K}}{300 \text{ K}} \right)^{14/0.4} = 935.3 \text{ kPa}
\]

The heat input is determined from

\[
s_2 - s_1 = c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} = -(0.287 \text{ kJ/kg} \cdot \text{K}) \ln \frac{935.3 \text{ kPa}}{2000 \text{ kPa}} = 0.2181 \text{ kJ/kg} \cdot \text{K}
\]

\[
Q_m = mT_H (s_2 - s_1) = (0.003 \text{ kg})(900 \text{ K})(0.2181 \text{ kJ/kg} \cdot \text{K}) = 0.5889 \text{ kJ}
\]

Then,

\[
\eta_{th} = 1 - \frac{T_L}{T_H} = 1 - \frac{300 \text{ K}}{900 \text{ K}} = 66.7\%
\]

\[
W_{net, out} = \eta_{th} Q_m = (0.667)(0.5889 \text{ kJ}) = 0.393 \text{ kJ}
\]

9–23  An air-standard Carnot cycle is executed in a closed system between the temperature limits of 350 and 1200 K. The pressures before and after the isothermal compression are 150 and 300 kPa, respectively. If the net work output per cycle is 0.5 kJ, determine \((a)\) the maximum pressure in the cycle, \((b)\) the heat transfer to air, and \((c)\) the mass of air. Assume variable specific heats for air. Answers: \((a)\) 30,013 kPa, \((b)\) 0.706 kJ, \((c)\) 0.00296 kg

Solution  A Carnot cycle with specified temperature limits is considered. The maximum pressure in the cycle, the heat transfer to the working fluid, and the mass of the working fluid are to be determined.

Assumption  Air is an ideal gas with variable specific heats.

Analysis  \((a)\) In a Carnot cycle, the maximum pressure occurs at the beginning of the expansion process, which is state 1.
\( p_4 = 300 \text{ kPa}, T_1 = 1200 \text{ K}, T_4 = 350 \text{ K}, \)

**Evaluation of \( p_1, \)**

4-1 Isentropic process,

\[ T P^{(1-k)/k} = C, \]

Hence, \( T_1 P_1^{(1-k)/k} = T_4 P_4^{(1-k)/k} \)

\( (P_1/P_4)^{(1-k)/k} = T_4 / T_1 \)

Hence, \( P_1/P_4 = (T_4 / T_1)^{k/(1-k)} \)

\[ P_1 = P_4 * (T_4 / T_1)^{k/(1-k)} \]

\[ T_{\text{avg}} = (T_1 + T_4) / 2 = (1200 \text{ K} + 350 \text{ K}) / 2 = 775 \text{ K} \]

Hence, from Table A-2, \( k = (1.359 + 1.354) / 2 = 1.3565 \)

Hence, \( p_1 = 300 \text{ kPa} \ (350 \text{ K} / 1200 \text{ K})^{1.365/0.365} \)

i.e., \( p_1 = 30081.4 \text{ kPa} = p_{\text{max}} \)

(b) The heat input is determined from

\[ \eta_{\text{th}} = 1 - \frac{T_L}{T_H} = 1 - \frac{350 \text{ K}}{1200 \text{ K}} = 70.83\% \]

\[ Q_{\text{in}} = W_{\text{net, out}} / \eta_{\text{th}} = (0.5 \text{ kJ}) / (0.7083) = 0.706 \text{ kJ} \]

(c) Evaluation of mass of air,

\[ s_4 - s_3 = c_{p,avg} \ln \frac{T_4}{T_3} - R \ln \frac{P_4}{P_3} \ (\text{kJ/kg}) \]

i.e.,

\[ s_4 - s_3 = c_{p,avg} \ln \frac{350}{300} - R \ln \frac{300}{p_3} \ (\text{kJ/kg}) \]

\( = 0 \ (\text{As } T_4 = T_3) \)
\[ s_4 - s_3 = -(0.287 \text{ kJ/kg}) \ln \frac{300 \text{ kPa}}{150 \text{ kPa}} \]

Hence,
\[ s_4 - s_3 = -0.199 \frac{\text{kJ}}{\text{kg}} = s_2 - s_1 \]

9–24 Repeat Problem 9–23 using helium as the working fluid.

**Solution**  A Carnot cycle with specified temperature limits is considered. The maximum pressure in the cycle, the heat transfer to the working fluid, and the mass of the working fluid are to be determined.

**Assumption** Helium is an ideal gas with constant specific heats.

**Properties** The properties of helium at room temperature are \( R = 2.0769 \text{ kJ/kg·K} \) and \( k = 1.667 \) (Table A-2).

**Analysis** (a) In a Carnot cycle, the maximum pressure occurs at the beginning of the expansion process, which is state 1.

\[ \frac{T_1}{T_4} = \left( \frac{P_1}{P_4} \right)^{\frac{k-1}{k}} \]

or,
\[ P_1 = P_4 \left( \frac{T_1}{T_4} \right)^{\frac{k}{k-1}} = 300 \text{ kPa} \left( \frac{1200 \text{ K}}{350 \text{ K}} \right)^{\frac{1.667}{0.667}} = 6524 \text{ kPa} \]

(b) The heat input is determined from
\[ \eta_{\text{in}} = 1 - \frac{T_L}{T_H} = 1 - \frac{350 \text{ K}}{1200 \text{ K}} = 70.83\% \]
\[ Q_{\text{in}} = W_{\text{net, out}} / \eta_{\text{in}} = (0.5 \text{ kJ})/(0.7083) = 0.706 \text{ kJ} \]

(c) The mass of helium is determined from
\[ s_4 - s_3 = c_p \ln \frac{T_4}{T_3} - R \ln \frac{P_4}{P_3} = -(2.0769 \text{ kJ/kg·K}) \ln \frac{300 \text{ kPa}}{150 \text{ kPa}} = -1.4396 \text{ kJ/kg·K} \]
\[ s_4 - s_3 = 1.4396 \text{ kJ/kg·K} \]
\[ w_{\text{net, out}} = (s_2 - s_1)(T_H - T_L) = (1.4396 \text{ kJ/kg·K})(1200 - 350) \text{ K} = 1223.7 \text{ kJ/kg} \]
\[ m = \frac{W_{\text{net, out}}}{1223.7 \text{ kJ/kg}} = 0.5 \text{ kJ} = 0.000409 \text{ kg} \]
Consider a Carnot cycle executed in a closed system with air as the working fluid. The maximum pressure in the cycle is 800 kPa while the maximum temperature is 750 K. If the entropy increase during the isothermal heat rejection process is 0.25 kJ/kg \cdot K and the net work output is 100 kJ/kg, determine (a) the minimum pressure in the cycle, (b) the heat rejection from the cycle, and (c) the thermal efficiency of the cycle. (d) If an actual heat engine cycle operates between the same temperature limits and produces 5200 kW of power for an air flow rate of 90 kg/s, determine the second law efficiency of this cycle.
What four processes make up the ideal Otto cycle?

**Solution** The four processes that make up the Otto cycle are (1) isentropic compression, (2) \( v = \text{constant heat addition} \), (3) isentropic expansion, and (4) \( v = \text{constant heat rejection} \).
9–34 An ideal Otto cycle has a compression ratio of 8. At the beginning of the compression process, air is at 95 kPa and 27°C, and 750 kJ/kg of heat is transferred to air during the constant-volume heat-addition process. Taking into account the variation of specific heats with temperature, determine (a) the pressure and temperature at the end of the heat-addition process, (b) the net work output, (c) the thermal efficiency, and (d) the mean effective pressure for the cycle.

**Answers:** (a) 3898 kPa, 1539 K, (b) 392.4 kJ/kg, (c) 52.3 percent, (d) 495 kPa

**Solution** An ideal Otto cycle with air as the working fluid has a compression ratio of 8. The pressure and temperature at the end of the heat addition process, the net work output, the thermal efficiency, and the mean effective pressure for the cycle are to be determined.

**Assumptions** 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with variable specific heats.

**Properties** The gas constant of air is \( R = 0.287 \text{ kJ/kg K} \). The properties of air are given in Table A-17.

**Analysis** (a) Process 1–2: isentropic compression.

From Table A-17, for \( T_1 = 300 \) K,

\[ u_1 = 214.07 \text{ kJ/kg} \]

\[ T_1 v_1^{k-1} = C, \]

Hence, \( T_1 v_1^{k-1} = T_2 v_2^{k-1} \), Hence, \( T_2 = T_1 \left( \frac{v_1}{v_2} \right)^{k-1} \)

For \( T = 300 \) K, \( k = 1.4 \) (from Table A-2)

i.e., \( T_2 = 300 K \left( \frac{8}{1.4} \right)^{1.4} = 689.2 \) K

Hence, From Table A-17, for \( T_2 = 689.2 \) K, \( u_2 = 504.45 \) kJ/kg

From Ideal gas equation,

\( pv = RT \), Hence, \( p_2 v_2 / T_2 = p_1 v_1 / T_1 \)

Hence, \( p_2 = p_1 \left( \frac{v_1}{v_2} \right) \left( \frac{T_2}{T_1} \right) \)

Hence, \( p_2 = 95 \text{ kPa} \left( \frac{8}{689.2 K/300 K} \right) = 1745.97 \text{ kPa} \)
Process 2–3: \( \nu = \) constant heat addition.

\[ q_{23, in} = u_3 - u_2 = c_v(T_3 - T_2) \]

750 kJ/kg = \( 0.718 \text{ kJ/kg} \cdot \text{K} \left( T_3 - 689 \right) \text{K} \]

\[ T_3 = 1734 \text{ K} \]

\[
\frac{P_3 \nu_3}{T_3} = \frac{P_2 \nu_2}{T_2} \quad \Rightarrow \quad P_3 = \frac{T_3}{T_2} P_2 = \left( \frac{1734 \text{ K}}{689 \text{ K}} \right) (1745 \text{ kPa}) = 4392 \text{ kPa}
\]

(b) Process 3–4: isentropic expansion.

\[ T_4 = T_3 \left( \frac{\nu_3}{\nu_4} \right)^{k-1} = (1734 \text{ K}) \left( \frac{1}{8} \right)^{0.4} = 755 \text{ K} \]

Process 4–1: \( \nu = \) constant heat rejection.

\[ q_{out} = u_4 - u_1 = c_v(T_4 - T_1) = (0.718 \text{ kJ/kg} \cdot \text{K})(755 - 300) \text{K} = 327 \text{ kJ/kg} \]

\[ w_{\text{net,out}} = q_{in} - q_{out} = 750 - 327 = 423 \text{ kJ/kg} \]

(c) \( \eta_{th} = \frac{w_{\text{net,out}}}{q_{in}} = \frac{423 \text{kJ/kg}}{750 \text{kJ/kg}} = 56.4\% \)

\[ \nu_1 = \frac{RT_1}{P_1} = \frac{0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K} \left( 300 \text{ K} \right)}{95 \text{ kPa}} = 0.906 \text{ m}^3/\text{kg} = \nu_{\text{max}} \]

\[ \nu_{\text{min}} = \nu_2 = \frac{\nu_{\text{max}}}{r} \]

\[ \text{MEP} = \frac{w_{\text{net,out}}}{\nu_1 - \nu_2} = \frac{w_{\text{net,out}}}{\nu_1 (1 - 1/r)} = \frac{423 \text{ kJ/kg}}{(0.906 \text{ m}^3/\text{kg}) (1 - 1/8)} \left( \frac{\text{kPa} \cdot \text{m}^3}{\text{kJ}} \right) = 534 \text{ kPa} \]
Repeat Problem 9–34 using constant specific heats at room temperature.

**Solution** An ideal Otto cycle with air as the working fluid has a compression ratio of 8. The pressure and temperature at the end of the heat addition process, the net work output, the thermal efficiency, and the mean effective pressure for the cycle are to be determined.

**Assumptions** 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with constant specific heats.

**Properties** The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg·K}$, $c_v = 0.718 \text{ kJ/kg·K}$, $R = 0.287 \text{ kJ/kg·K}$, and $k = 1.4$ (Table A-2).

**Analysis (a)** Process 1–2: isentropic compression.

$$T_2 = T_1 \left( \frac{\nu_1}{\nu_2} \right)^{k-1} = (300 \text{ K}) \left( \frac{8}{8} \right)^{0.4} = 689 \text{ K}$$

$$\frac{P_2\nu_2}{T_2} = \frac{P_1\nu_1}{T_1} \Rightarrow P_2 = \frac{\nu_1}{\nu_2} \frac{T_2}{T_1} P_1 = (8 \left( \frac{689 \text{ K}}{300 \text{ K}} \right))(95 \text{ kPa}) = 1745 \text{ kPa}$$

Process 2–3: $v = \text{constant heat addition}$

$$q_{23,\text{in}} = u_3 - u_2 = c_v(T_3 - T_2)$$

$$750 \text{ kJ/kg} = (0.718 \text{ kJ/kg·K})(T_3 - 689)$$

$$T_3 = 1734 \text{ K}$$

$$\frac{P_3\nu_3}{T_3} = \frac{P_2\nu_2}{T_2} \Rightarrow P_3 = \frac{T_3}{T_2} P_2 = \left( \frac{1734 \text{ K}}{689 \text{ K}} \right)(1745 \text{ kPa}) = 4392 \text{ kPa}$$

**Analysis (b)** Process 3–4: isentropic expansion.

$$T_4 = T_3 \left( \frac{\nu_3}{\nu_4} \right)^{k-1} = (1734 \text{ K}) \left( \frac{1}{8} \right)^{0.4} = 755 \text{ K}$$

Process 4–1: $v = \text{constant heat rejection}$

$$q_{\text{out}} = u_4 - u_1 = c_v(T_4 - T_1) = (0.718 \text{ kJ/kg·K})(755 - 300) = 327 \text{ kJ/kg}$$

$$w_{\text{net.out}} = q_{\text{in}} - q_{\text{out}} = 750 - 327 = 423 \text{ kJ/kg}$$

$$\eta_{\text{th}} = \frac{w_{\text{net.out}}}{q_{\text{in}}} = \frac{423 \text{ kJ/kg}}{750 \text{ kJ/kg}} = 56.4\%$$

**Analysis (c)**

$$v_1 = \frac{RT_1}{P_1} = \left( \frac{0.287 \text{ kPa·m}^3/\text{kg·K}}{95 \text{ kPa}} \right)(300 \text{ K}) = 0.906 \text{ m}^3/\text{kg} = v_{\text{max}}$$

$$v_{\text{max}} = v_2 = \frac{v_{\text{max}}}{r}$$

$$\text{MEP} = \frac{w_{\text{net.out}}}{v_1 - v_2} - \frac{w_{\text{net.out}}}{v_1(1 - 1/r)} - \frac{423 \text{ kJ/kg}}{0.906 \text{ m}^3/\text{kg}(1-1/8)} \left( \frac{\text{kPa·m}^3}{\text{kJ}} \right) = 554 \text{ kPa}$$
9–37 The compression ratio of an air-standard Otto cycle is 9.5. Prior to the isentropic compression process, the air is at 100 kPa, 35°C, and 600 cm$^3$. The temperature at the end of the isentropic expansion process is 800 K. Using specific heat values at room temperature, determine (a) the highest temperature and pressure in the cycle; (b) the amount of heat transferred in, in kJ; (c) the thermal efficiency; and (d) the mean effective pressure. Answers: (a) 1969 K, 6072 kPa, (b) 0.59 kJ, (c) 59.4 percent, (d) 652 kPa

Solution

An ideal Otto cycle with air as the working fluid has a compression ratio of 9.5. The highest pressure and temperature in the cycle, the amount of heat transferred, the thermal efficiency, and the mean effective pressure are to be determined.

Assumptions 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $c_p = 1.005$ kJ/kg·K, $c_v = 0.718$ kJ/kg·K, $R = 0.287$ kJ/kg·K, and $k = 1.4$ (Table A-2).

Analysis

(a) Process 1–2: isentropic compression.

$$T_2 = T_1 \left( \frac{v_1}{v_2} \right)^{\frac{1}{k-1}} = (308 \text{ K})(9.5)^{\frac{1}{4}} = 757.9 \text{ K}$$

$$\frac{P_2 v_2}{T_2} = \frac{P_1 v_1}{T_1} \rightarrow P_2 = \frac{v_1}{v_2} T_2 P_1 = (9.5) \left( \frac{757.9 \text{ K}}{308 \text{ K}} \right)(100 \text{ kPa}) = 2338 \text{ kPa}$$

Process 3–4: isentropic expansion.

$$T_4 = T_3 \left( \frac{v_4}{v_3} \right)^{\frac{1}{k-1}} = (800 \text{ K})(9.5)^{\frac{1}{4}} = 1969 \text{ K}$$

Process 2-3: $\nu = $ constant heat addition.

$$\frac{P_3 v_3}{T_3} = \frac{P_2 v_2}{T_2} \rightarrow P_3 = \frac{T_3}{T_2} P_2 = \frac{1969 \text{ K}}{757.9 \text{ K}} (2338 \text{ kPa}) = 6072 \text{ kPa}$$

(b) $m = \frac{P_1 v_1}{RT_1} = \frac{(100 \text{ kPa})(0.0006 \text{ m}^3)}{(0.287 \text{ kJ/kg·K})(308 \text{ K})} = 6.788 \times 10^{-4} \text{ kg}$

$$Q_{in} = m(u_3 - u_2) = mc_v(T_3 - T_2) = (6.788 \times 10^{-4} \text{ kg})(0.718 \text{ kJ/kg·K})(1969 - 757.9) \text{ K} = 0.590 \text{ kJ}$$

(c) Process 4–1: $\nu = $ constant heat rejection.

$$Q_{out} = m(u_4 - u_1) - mc_v(T_4 - T_1) = -6.788 \times 10^{-4} \text{ kg}(0.718 \text{ kJ/kg·K})(800 - 308) \text{ K} = -0.240 \text{ kJ}$$

$$W_{net} = Q_{in} - Q_{out} = 0.590 - 0.240 = 0.350 \text{ kJ}$$

$$\eta_{th} = \frac{W_{net}}{Q_{in}} = \frac{0.350 \text{ kJ}}{0.590 \text{ kJ}} = 59.4\%$$

(d) $\nu_{min} = \nu_2 = \frac{\nu_{max}}{r}$

$$\text{MEP} = \frac{W_{net, out}}{\nu_1 - \nu_2} = \frac{W_{net, out}}{(0.0006 \text{ m}^3)(1-1/9.5)} = \frac{0.350 \text{ kJ}}{762 \text{ kPa·m}^3} = 662 \text{ kPa}$$
9–38 Repeat Problem 9–37, but replace the isentropic expansion process by a polytropic expansion process with the polytropic exponent $n = 1.35$. 
Solution

An Otto cycle with air as the working fluid has a compression ratio of 9.5. The highest pressure and temperature in the cycle, the amount of heat transferred, the thermal efficiency, and the mean effective pressure are to be determined.

Assumptions
1. The air-standard assumptions are applicable.
2. Kinetic and potential energy changes are negligible.
3. Air is an ideal gas with constant specific heats.

Properties
The properties of air at room temperature are \( c_p = 1.005 \text{ kJ/kg\cdotK} \), \( c_v = 0.718 \text{ kJ/kg\cdotK} \), \( R = 0.287 \text{ kJ/kg\cdotK} \), and \( k = 1.4 \) (Table A-2).

Analysis (a) Process 1–2: isentropic compression.

\[
T_2 = T_1 \left( \frac{\nu_1}{\nu_2} \right)^{\frac{k}{k-1}} = (308 \text{ K})(9.5)^{0.4} = 757.9 \text{ K}
\]

\[
\frac{P_2 \nu_2}{T_2} = \frac{P_1 \nu_1}{T_1} \quad \Rightarrow \quad P_2 = \frac{\nu_1}{\nu_2} P_1 \quad R_1 = \left( \frac{757.9 \text{ K}}{308 \text{ K}} \right)(100 \text{ kPa}) = 2338 \text{ kPa}
\]

Process 3–4: polytropic expansion.

\[
m = P_4 \nu_4
\]

\[
R T_1 = \frac{(100 \text{ kPa})(0.0006 \text{ m}^3)}{(0.287 \text{ kJ/kg\cdotm}^3)(308 \text{ K})} = 6.788 \times 10^{-4} \text{ kg}
\]

\[
T_3 = T_4 \left( \frac{\nu_4}{\nu_3} \right)^{\frac{n-1}{n}} = (800 \text{ K})(9.5)^{0.35} = 1759 \text{ K}
\]

\[
W_{34} = m \left( \frac{R}{1-n} \right) \left( \frac{T_4 - T_3}{T_4 - T_3} \right) = \left( 6.788 \times 10^{-4} \right)(0.287 \text{ kJ/kg\cdotK})(800-1759) \text{ K} = 0.5338 \text{ kJ}
\]

Then energy balance for process 3–4 gives

\[
E_{in} - E_{out} = \Delta E_{system}
\]

\[
Q_{34, in} - W_{34, out} = m(u_4 - u_3)
\]

\[
Q_{34, in} = m(u_4 - u_3) + W_{34, out} = mc_v(T_4 - T_3) + W_{34, out}
\]

\[
Q_{34, in} = (6.788 \times 10^{-4} \text{ kg})(0.718 \text{ kJ/kg\cdotK})(800-1759) \text{ K} + 0.5338 \text{ kJ} = 0.0064 \text{ kJ}
\]

That is, 0.066 kJ of heat is added to the air during the expansion process (This is not realistic, and probably is due to assuming constant specific heats at room temperature).

(b) Process 2–3: \( v \) = constant heat addition.

\[
\frac{P_3 \nu_3}{T_3} = \frac{P_2 \nu_2}{T_2} \quad \Rightarrow \quad P_3 = \frac{T_3}{T_2} P_2 = \left( \frac{1759 \text{ K}}{757.9 \text{ K}} \right)(2338 \text{ kPa}) = 5426 \text{ kPa}
\]

\[
Q_{23, in} = m(u_3 - u_2) = mc_v(T_3 - T_2)
\]

\[
Q_{23, in} = (6.788 \times 10^{-4} \text{ kg})(0.718 \text{ kJ/kg\cdotK})(1759 - 757.9) \text{ K} = 0.4879 \text{ kJ}
\]

Therefore,

\[
Q_{in} = Q_{23, in} + W_{34, in} = 0.4879 + 0.0064 = 0.5543 \text{ kJ}
\]

(c) Process 4–1: \( v \) = constant heat rejection.

\[
Q_{out} = m(u_4 - u_1) = mc_v(T_4 - T_1)
\]

\[
W_{net, out} = Q_{in} - Q_{out} = 0.5543 - 0.2398 = 0.3145 \text{ kJ}
\]

\[
\eta_{th} = \frac{W_{net, out}}{Q_{in}} = \frac{0.3145 \text{ kJ}}{0.5543 \text{ kJ}} = 56.7\%
\]

(d) \( V_{max} = V_1 = \frac{\nu_{max}}{r} \)

\[
\frac{W_{net, out}}{V_1 - V_2} = \frac{W_{net, out}}{V_1(1-1/r)} = \frac{0.3145 \text{ kJ}}{(0.0006 \text{ m}^3)(1-1/9.5)} \left( \frac{\text{kPa} \cdot \text{m}^3}{\text{kJ}} \right) = 586 \text{ kPa}
\]
9–42C How does a diesel engine differ from a gasoline engine?

Solution A diesel engine differs from the gasoline engine in the way combustion is initiated. In diesel engines combustion is initiated by compressing the air above the self-ignition temperature of the fuel whereas it is initiated by a spark plug in a gasoline engine.

9–43C How does the ideal Diesel cycle differ from the ideal Otto cycle?

Solution The Diesel cycle differs from the Otto cycle in the heat addition process only; it takes place at constant volume in the Otto cycle, but at constant pressure in the Diesel cycle.

9–47 An air-standard Diesel cycle has a compression ratio of 16 and a cutoff ratio of 2. At the beginning of the compression process, air is at 95 kPa and 27°C. Accounting for the variation of specific heats with temperature, determine (a) the temperature after the heat-addition process, (b) the thermal efficiency, and (c) the mean effective pressure.

Answers: (a) 1724.8 K, (b) 56.3 percent, (c) 675.9 kPa

Solution An air-standard Diesel cycle with a compression ratio of 16 and a cutoff ratio of 2 is considered. The temperature after the heat addition process, the thermal efficiency, and the mean effective pressure are to be determined.

Assumptions 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with variable specific heats.

Properties The gas constant of air is \( R = 0.287 \text{ kJ/kg.K} \). The properties of air are given in Table A-17.

Analysis (a) Process 1–2: isentropic compression.

\[ p_1 = 95 \text{ kPa}, \quad T_1 = 27 + 273 = 300 \text{ K}, \]
\( p_1 v_1 = RT_1 \), Hence, \( v_1 = \frac{RT_1}{p_1} = \frac{(0.287 \text{ kJ/kgK} \times 300 \text{ K} / 95 \text{ kPa})}{0.906 \text{ m}^3/\text{kg}} = \nu_d = \nu_{\text{max}}. \)

From Table A-17, for \( T_1 = 300 \text{ K} \), \( u_1 = 214.07 \text{ kJ/kg} \)

\[ TV^{k-1} = C, \]

Hence, \( T_1 v_1^{k-1} = T_2 v_2^{k-1} \), Hence, \( T_2 = T_1 \left( \frac{v_1}{v_2} \right)^{k-1} \)

, Temperature after heat addition; \( T_2 = 300 \text{ K} \) \((16)^{1.4-1} = 909.43 \text{ K} \)

Compression ratio = 16; \( \frac{v_2}{v_1} = 1/16 = 0.0625 \), Hence, \( v_2 = 0.0566 \text{ m}^3/\text{kg} \)

\[ P_2 v_2 = RT_2 \), Hence, \( p_2 = \frac{RT_2}{v_2} = \frac{(0.287 \text{ kJ/kgK} \times 909.43 \text{ K}}{0.0566 \text{ m}^3/\text{kg}}) = 4609.4 \text{ kPa}. \]

From Table A-17, for \( T_2 = 909.43 \text{ K} \), \( h_2 \) is evaluated by interpolation,

\[ (h_2 - 932.93)/955.38 = (909.43 - 900)/(920 - 900) \]

Hence, \( h_2 = 943.52 \text{ kJ/kg} \)

Process 2-3 is constant pressure heat addition,
Hence, \( p_3 = p_2 = 4609.4 \text{ kPa} \)

From Ideal gas relation,
\[ pv = RT \), Hence, \( p_3 v_3/T_3 = p_2 v_2/T_2 \)

, \( T_3 = T_2 (\frac{v_3}{v_2}) = 909.43 \text{ K} \) \((2) = 1818.86 \text{ K} \)

, From Table A-17, for \( T_3 = 1818.86 \text{ K} \), \( h_3 \) is evaluated by interpolation,

\[ (h_3 - 2003.3)/(2065.3 - 2003.3) = (1818.86 - 1800)/(1850 - 1800) \]

Hence, \( h_3 = 2026.7 \text{ kJ/kg} \)

\[ v_3/v_2 = 2 \), \( v_3/0.0566 \text{ m}^3/\text{kg} = 2. \) Hence, \( v_3 = 0.1132 \text{ m}^3/\text{kg} \)

\((b), q_{\text{in}} = h_3 - h_2 = 2026.7 \text{ kJ/kg} - 943.52 \text{ kJ/kg} = 1083.17 \text{ kJ/kg} \)

Process 3-4 is isentropic expansion,

\( \text{From Table A-17, for } T = T_3 = 1818.86 \text{ K}, k \approx 1.336 \)

\( p_4 v_4^k = p_3^k v_3^k \), Hence, \( p_4 = p_3 (\frac{v_4}{v_3})^k = 4609.4 \text{ kPa} \)

\( 0.1132 \text{ m}^3/\text{kg} / 0.906 \text{ m}^3/\text{kg} \) \(^{1.336} = 286.3254 \text{ kPa} \)

\( p_4 v_4 = RT_4 \), Hence, \( T_4 = (p_4 v_4 / R) = (286.3254 \text{ kPa} \times 0.906 \text{ m}^3/\text{kg} / 0.287 \text{ kJ/kgK}) = 903.87 \text{ K} \)

\( \text{From Table A-17, for } T = T_4 = 903.87 \text{ K}, \) \( u_4 \) is evaluated by interpolation,

\( (u_4 - 674.58)/(691.28 - 674.58) = (903.87 - 900)/(920 - 900) \)
\[ u_4 = 677.811 \text{ kJ/kg} \]

\[ q_{out} = u_4 - u_1 = 677.811 \text{ kJ/kg} - 214.07 \text{ kJ/kg} = 463.74 \text{ kJ/kg} \]

But, \( \eta_{th} = (1 - q_{out} / q_{in}) \)

\[ \eta_{th} = 0.571866 \times 100\% = 57.19 \% \]

(c), \( w_{net, out} = q_{in} - q_{out} = 1083.17 \text{ kJ/kg} - 463.74 \text{ kJ/kg} = 619.43 \text{ kJ/kg} \)

\[ MEP = \frac{w_{net, out}}{(v_1 - v_2)} = 619.43 \text{ kJ/kg} / (0.906 \text{ m}^3/\text{kg} - 0.0566 \text{ m}^3/\text{kg}) \]

\[ Hence, MEP = 729.256 \text{ kPa} \]

9–48 Repeat Problem 9–47 using constant specific heats at room temperature.
An ideal diesel engine has a compression ratio of 20 and uses air as the working fluid. The state of air at the beginning of the compression process is 95 kPa and 20°C. If the maximum temperature in the cycle is not to exceed 2200 K, determine (a) the thermal efficiency and (b) the mean effective pressure. Assume constant specific heats for air at room temperature. Answers: (a) 63.5 percent, (b) 933 kPa
9–52 Repeat Problem 9–51, but replace the isentropic expansion process by polytropic expansion process with the polytropic exponent $n = 1.35$. 

Solution

An ideal diesel engine with air as the working fluid has a compression ratio of 20. The thermal efficiency and the mean effective pressure are to be determined.

**Assumptions** 1. The air-standard assumptions are applicable. 2. Kinetic and potential energy changes are negligible. 3. Air is an ideal gas with constant specific heats.

**Properties** The properties of air at room temperature are $c_p = 1.005$ kJ/kg·K, $c_v = 0.718$ kJ/kg·K, $R = 0.287$ kJ/kg·K, and $k = 1.4$ (Table A-2).

**Analysis** (a) Process 1–2: isentropic compression.

$$T_2 = T_1 \left( \frac{V_1}{V_2} \right)^{k-1} = (293 \text{ K})(20)^{0.4} = 971.1 \text{ K}$$

Process 2–3: $P$ = constant heat addition.

$$\frac{P_3 V_3}{T_3} = \frac{P_2 V_2}{T_2} \quad \frac{V_3}{V_2} = \frac{T_3}{T_2} = \frac{2200 \text{ K}}{971.1 \text{ K}} = 2.265$$

Process 3–4: isentropic expansion

$$T_4 = T_3 \left( \frac{V_3}{V_4} \right)^{k-1} = T_3 \left( \frac{2.265 V_2}{V_4} \right)^{k-1} - T_3 \left( \frac{2.265}{r} \right)^{k-1} - (2200 \text{ K}) \left( \frac{2.265}{20} \right)^{0.4} - 920.6 \text{ K}$$

$$q_{in} - h_3 - h_2 = c_p(T_3 - T_2) = (1.005 \text{ kJ/kg·K})(2200 - 971.1) \text{ K} = 1235 \text{ kJ/kg}$$

$$q_{out} = u_4 - u_1 = c_v(T_4 - T_1) = (0.718 \text{ kJ/kg·K})(920.6 - 293) \text{ K} = 450.6 \text{ kJ/kg}$$

$$w_{net, out} = q_{in} - q_{out} = 1235 - 450.6 = 784.4 \text{ kJ/kg}$$

$$\eta_{th} = \frac{w_{net, out}}{q_{in}} = \frac{784.4 \text{ kJ/kg}}{1235 \text{ kJ/kg}} = 63.5\%$$

(b) $V_1 = \frac{RT_1}{P_1} = \frac{(0.287 \text{ kPa·m}^3/\text{kg·K})(293 \text{ K})}{95 \text{ kPa}} = 0.885 \text{ m}^3/\text{kg} = V_{max}$

$$V_{min} - V_2 = \frac{V_{max}}{r}$$

$$mEP = \frac{w_{net, out}}{V_1 - V_2} = \frac{w_{net, out}}{V_1(1 - 1/r)} = \frac{784.4 \text{ kJ/kg}}{(0.885 \text{ m}^3/\text{kg})(1-1/20)} = 933 \text{ kPa}$$
A diesel engine with air as the working fluid has a compression ratio of 20. The thermal efficiency and the mean effective pressure are to be determined.

Assumptions 1. The air-standard assumptions are applicable. 2. Kinetic and potential energy changes are negligible. 3. Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are \( c_p = 1.005 \text{ kJ/kg} \cdot \text{K} \), \( c_v = 0.718 \text{ kJ/kg} \cdot \text{K} \), and \( k = 1.4 \) (Table A-2).

Analysis (a) Process 1–2: isentropic compression.
\[
T_2 = T_1 \left( \frac{\nu_1}{\nu_2} \right)^{k-1} = (293 \text{ K})(20)^{0.4} = 971.1 \text{ K}
\]

Process 2–3: \( P = \) constant heat addition.
\[
\frac{P_2\nu_2}{T_3} = \frac{P_1\nu_1}{T_2} \quad \frac{\nu_2}{\nu_2} = \frac{T_3}{T_2} = \frac{2200 \text{ K}}{971.1 \text{ K}} = 2.265
\]

Process 3–4: polytropic expansion.
\[
T_4 = T_3 \left( \frac{\nu_3}{\nu_4} \right)^{n-1} = T_3 \left( \frac{2.265\nu_2}{\nu_4} \right)^{n-1} = T_3 \left( \frac{2.265}{r} \right)^{n-1} = (2200 \text{ K}) \left( \frac{2.265}{20} \right)^{0.35} = 1026 \text{ K}
\]

\( q_{\text{in}} = h_3 - h_2 = c_p(T_3 - T_2) = (1.005 \text{ kJ/kg} \cdot \text{K})(2200 - 971.1) \text{ K} = 1235 \text{ kJ/kg} \)

\( q_{\text{out}} = h_4 - h_1 = c_v(T_4 - T_1) = (0.718 \text{ kJ/kg} \cdot \text{K})(1026 - 293) \text{ K} = 526.3 \text{ kJ/kg} \)

Note that \( q_{\text{out}} \) in this case does not represent the entire heat rejected since some heat is also rejected during the polytropic process, which is determined from an energy balance in process 3–4:
\[
w_{34,\text{out}} = \frac{R(T_4 - T_1)}{1 - n} = (0.287 \text{ kJ/kg} \cdot \text{K})(1026 - 2200) \text{ K} = 963 \text{ kJ/kg}
\]
\[
E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{cylinder}}
\]
\[
q_{34,\text{in}} = w_{34,\text{out}} + c_p(T_4 - T_3) = 963 \text{ kJ/kg} + (0.718 \text{ kJ/kg} \cdot \text{K})(1026 - 2200) \text{ K} = 120.1 \text{ kJ/kg}
\]

which means that 120.1 kJ/kg of heat is transferred to the combustion gases during the expansion process. This is unrealistic since the gas is at a much higher temperature than the surroundings, and a hot gas loses heat during polytropic expansion. The cause of this unrealistic result is the constant specific heat assumption. If we were to use \( c_v \) data from the air table, we would obtain
\[
q_{34,\text{in}} = w_{34,\text{out}} + (n_4 - n_3) = 963 + (7813 - 1872.4) = -128.1 \text{ kJ/kg}
\]
which is a heat loss as expected. Then \( q_{\text{out}} \) becomes
\[
q_{\text{out}} = q_{34,\text{out}} + q_{\text{ad1, out}} = 128.1 + 526.3 = 654.4 \text{ kJ/kg}
\]
and
\[
w_{\text{net, out}} = q_{\text{in}} - q_{\text{out}} = 1235 - 654.4 = 580.6 \text{ kJ/kg}
\]
\[
\eta_{\text{th}} = \frac{w_{\text{net, out}}}{q_{\text{in}}} = \frac{580.6 \text{ kJ/kg}}{1235 \text{ kJ/kg}} = 47.0 \%
\]

(b) \[
\nu_1 = \frac{RT_1}{P_1} = \frac{(0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(293 \text{ K})}{95 \text{ kPa}} = 0.885 \text{ m}^3/\text{kg} = \nu_{\text{max}}
\]
\[
\nu_{\text{min}} = \nu_2 = \frac{\nu_{\text{max}}}{r}
\]
\[
\text{MEP} = \frac{w_{\text{net, out}}}{\nu_1 - \nu_2} = \frac{w_{\text{net, out}}}{\nu_1(1-1/r)} = \frac{580.6 \text{ kJ/kg}}{(0.885 \text{ m}^3/\text{kg})(1-1/20)} \left( \frac{1 \text{ kPa} \cdot \text{m}^3}{1 \text{ kJ}} \right) = 691 \text{ kPa}
\]
The compression ratio of an ideal dual cycle is 14. Air is at 100 kPa and 300 K at the beginning of the compression process and at 2200 K at the end of the heat-addition process. Heat transfer to air takes place partly at constant volume and partly at constant pressure, and it amounts to 1520.4 kJ/kg. Assuming variable specific heats for air, determine (a) the fraction of heat transferred at constant volume and (b) the thermal efficiency of the cycle.

**Solution**  
An ideal dual cycle with air as the working fluid has a compression ratio of 14. The fraction of heat transferred at constant volume and the thermal efficiency of the cycle are to be determined.

**Assumptions**  
1. The air standard assumptions are applicable.  
2. Kinetic and potential energy changes are negligible.  
3. Air is an ideal gas with variable specific heats.

**Properties**  
The properties of air are given in Table A-17.

**Analysis**  
(a) Process 1-2: isentropic compression

From Table, A-17, For $T_1 = 300$ K, $u_1 = 214.07$ kJ/kg,

$p_1 = 100$ kPa,

$p_1 v_1 = RT_1$, Hence, $v_1 = (RT_1/p_1) = (0.287$ kJ/kgK * $300$ K / $100$ kPa) = 0.861 m$^3$/kg = $v_4 = v_{max}$.

Compression ratio $= 14$; $v_2/v_1 = 1/14$, Hence, $v_2 = 0.0615$ m$^3$/kg

$T v^{k-1} = C$,

Hence, $T_1 v_1^{k-1} = T_2 v_2^{k-1}$, Hence, $T_2 = T_1 (v_1/v_2)^{k-1}$

Temperature after heat addition; $T_2 = 300 K (14)^{1.4-1} = 862.13$ K

From Table, A-17, For $T_2 = 862.13$ K, $u_2$ is evaluated by interpolation,

$u_2 = 641.40 + (657.95 - 641.40)/(880 - 860) (862.13 - 860) = 643.163$ kJ/kg,

Process 2-x is constant volume heat addition,

Process x-3 is constant pressure heat addition,
, $T_3 = 2200 \text{ K (I/P data),}$

From Table, A-17, For $T_3 = 2200 \text{ K}$, $h_3 = 2503.2 \text{ kJ/kg}$,

$q_{in} = q_{2-x,\text{in}} + q_{3-x,\text{in}} = (u_x - u_2) + (h_3 - h_x)$

Hence,

$1520.4 \text{ kJ/kg} = (u_x - 611.2) + (2503.2 - h_x)$

By trial and error, we get $T_x = 1300 \text{ K}$ and $h_x = 1395.97$, $u_x = 1022.82 \text{ kJ/kg}$.

Thus,

$q_{2-x,\text{in}} = u_x - u_2 = 1022.82 - 611.2 = 411.62 \text{ kJ/kg}$

and

$ratio = \frac{q_{2-x,\text{in}}}{q_{in}} = \frac{411.62 \text{ kJ/kg}}{1520.4 \text{ kJ/kg}} = 27.1\%$

Process 2-x is constant volume heat addition,

Hence, $v_x = v_2 = 0.0615 \text{ m}^3/\text{kg}$

Hence, $v_3 = 1.692 \times 0.0615 \text{ m}^3/\text{kg} = 0.10406 \text{ m}^3/\text{kg}$

$p_3 v_3 = RT_3$ , Hence, $p_3 = \frac{RT_3}{v_3} = \frac{0.287 \text{ kJ/kgK} \times 2200 \text{ K}}{0.10406 \text{ m}^3/\text{kg}}$

$p_3 v_3 = 2200 \text{ K} \times 1.692 = 360.53 \text{ kPa}$

Process 3-4 is isentropic process, Hence, $p_3 v_3^k = p_4 v_4^k$

From Table A-2c, For $T_3 = 2200 \text{ K}$, $k = 1.336$

Hence, $p_4 = p_3 \left( \frac{v_3}{v_4} \right)^k = p_3 (v_3/v_4)^k = 6067.77 \text{ kPa} \times 0.10406 \text{ m}^3/\text{kg} / 0.861 \text{ m}^3/\text{kg} \times 1.336 = 360.53 \text{ kPa}$

$p_4 v_4 = RT_4$ , Hence, $T_4 = (p_4 v_4 / R) = (360.53 \text{ kPa} \times 0.861 \text{ m}^3/\text{kg} / 0.287 \text{ kJ/kgK}) = 1081.6 \text{ K}$

From Table, A-17, For $T_4 = 1081.6 \text{ K}$, $u_4 \approx 828 \text{ kJ/kg}$,

Process 4-1 is constant volume heat rejection,

$q_{out} = u_4 - u_1 = 828 \text{ kJ/kg} - 214.07 \text{ kJ/kg} = 614.0 \text{ kJ/kg}$

$\eta_{th} = 1 - \left( \frac{q_{out}}{q_{in}} \right) = 214.07 \text{ kJ/kg} / (614.0 \text{ kJ/kg} / 1520.4 \text{ kJ/kg}) = 59.6\%$

9–58 Repeat Problem 9–56 using constant specific heats at room temperature. Is the constant specific heat assumption reasonable in this case?
9–60C Consider the ideal Otto, Stirling, and Carnot cycle operating between the same temperature limits. How would you compare the thermal efficiencies of these three cycles?

Solution The efficiencies of the Carnot and the Stirling cycles would be the same, the efficiency of the Otto cycle would be less.

9–61C Consider the ideal Diesel, Ericsson, and Carnot cycles operating between the same temperature limits. How would you compare the thermal efficiencies of these three cycles?

Solution The efficiencies of the Carnot and the Ericsson cycles would be the same, the efficiency of the Diesel cycle would be less.

9–65 Consider an ideal Ericsson cycle with air as the working fluid executed in a steady-flow system. Air is at 27°C and 120 kPa at the beginning of the isothermal compression process, during which 150 kJ/kg of heat is rejected. Heat transfer to air occurs at 1200 K. Determine (a) the maximum pressure in the cycle, (b) the net work output per unit mass of air, and (c) the thermal efficiency of the cycle. Answers: (a) 685 kPa, (b) 450 kJ/kg, (c) 75 percent
An ideal Stirling engine using helium as the working fluid operates between temperature limits of 300 and 2000 K and pressure limits of 150 kPa and 3 MPa. Assuming the mass of the helium used in the cycle is 0.12 kg, determine (a) the thermal efficiency of the cycle, (b) the amount of heat transfer in the regenerator, and (c) the work output per cycle.

Solution

An ideal steady-flow Ericsson engine with air as the working fluid is considered. The maximum pressure in the cycle, the net work output, and the thermal efficiency of the cycle are to be determined.

Assumption Air is an ideal gas.

Properties The gas constant of air is \( R = 0.287 \text{ kJ/kg·K} \) (Table A-1).

Analysis (a) The entropy change during process 3-4 is

\[
s_4 - s_3 = \frac{q_{34,\text{out}}}{T_0} = -\frac{150 \text{ kJ/kg}}{300 \text{ K}} = -0.5 \text{ kJ/kg·K}
\]

(As \( T_4 = T_3 \))

\[
s_4 - s_3 = c_p \ln \frac{T_4}{T_3} - R \ln \frac{P_4}{P_3}
\]

and

\[
-0.287 \text{ kJ/kg·K} \ln \frac{P_4}{120 \text{ kPa}} = -0.5 \text{ kJ/kg·K}
\]

It yields \( P_4 = 685.2 \text{ kPa} \)

(b) For reversible cycles, \( \frac{q_{\text{out}}}{q_m} = \frac{T_L}{T_H} \rightarrow q_m = \frac{T_H}{T_L} q_{\text{out}} = \frac{1200 \text{ K}}{300 \text{ K}} (150 \text{ kJ/kg}) = 600 \text{ kJ/kg} \)

Thus, \( w_{\text{net,\text{out}}} = q_m - q_{\text{out}} = 600 - 150 = 450 \text{ kJ/kg} \)

(c) The thermal efficiency of this totally reversible cycle is determined from

\[
\eta_{\text{th}} = 1 - \frac{T_L}{T_H} = 1 - \frac{300 \text{ K}}{1200 \text{ K}} = 75.0\%
\]

9–66 An ideal Stirling engine using helium as the working fluid operates between temperature limits of 300 and 2000 K and pressure limits of 150 kPa and 3 MPa. Assuming the mass of the helium used in the cycle is 0.12 kg, determine (a) the thermal efficiency of the cycle, (b) the amount of heat transfer in the regenerator, and (c) the work output per cycle.
A simple Brayton cycle using air as the working fluid has a pressure ratio of 8. The minimum and maximum temperatures in the cycle are 310 and 1160 K. Assuming an isentropic efficiency of 75 percent for the compressor and 82 percent for the turbine, determine (a) the air temperature at the turbine exit, (b) the net work output, and (c) the thermal efficiency.

**Solution**

An ideal Stirling engine with helium as the working fluid operates between the specified temperature and pressure limits. The thermal efficiency of the cycle, the amount of heat transfer in the regenerator, and the work output per cycle are to be determined.

**Assumption**

Helium is an ideal gas with constant specific heats.

**Properties**

The gas constant and the specific heat of helium at room temperature are \( R = 2.0769 \text{ kJ/kg.K} \), \( c_v = 3.1156 \text{ kJ/kg.K} \), \( c_p = 5.1926 \text{ kJ/kg.K} \) (Table A-2).

**Analysis**

(a) The thermal efficiency of this totally reversible cycle is determined from

\[
\eta_{th} = 1 - \frac{T_L}{T_H} = 1 - \frac{300 \text{ K}}{2700 \text{ K}} = 85.0\% 
\]

(b) The amount of heat transferred in the regenerator is

\[
Q_{regen} = m(u_4 - u_1) = m c_v(T_1 - T_4) = 0.12 \text{ kg}(3.1156 \text{ kJ/kg.K})(2000 - 300)\text{ K}
\]

\[= 635.6 \text{ kJ} \]

(c) The net work output is determined from

\[
\frac{P_3 v_3}{T_3} = \frac{P_1 v_1}{T_1} \rightarrow \frac{v_3}{v_1} = \frac{P_2 P_1}{P_1 P_3} = 3 \text{ (As } T_2 = T_1 \text{)}
\]

\[s_2 - s_1 = c_v \ln \frac{T_2}{T_1} + R \ln \frac{v_2}{v_1} = (2.0769 \text{ kJ/kg.K})(\ln 3) = 2.282 \text{ kJ/kg.K} \]

\[Q_{in} = m T_H (s_2 - s_1) = 0.12 \text{ kg}(2000 \text{ K})(2.282 \text{ kJ/kg.K}) = 547.6 \text{ kJ} \]

\[W_{net,out} = \eta_{th} Q_{in} = (0.85)(547.6 \text{ kJ}) = 465.5 \text{ kJ} \]

9–73 A simple Brayton cycle using air as the working fluid has a pressure ratio of 8. The minimum and maximum temperatures in the cycle are 310 and 1160 K.

Assuming an isentropic efficiency of 75 percent for the compressor and 82 percent for the turbine, determine (a) the air temperature at the turbine exit, (b) the net work output, and (c) the thermal efficiency.

**Solution**

A simple Brayton cycle with air as the working fluid has a pressure ratio of 8. The air temperature at the turbine exit, the net work output, and the thermal efficiency are to be determined.

**Assumptions**

1. Steady operating conditions exist.
2. The air standard assumptions are applicable.
3. Kinetic and potential energy changes are negligible.
4. Air is an ideal gas with variable specific heats.

**Properties**

The properties of air are given in Table A-17.

**Analysis**

(a) Noting that process 1–2 is isentropic,

1) Evaluation of Temperature at turbine exit; \( T_4 \)

From Table A-2b, for \( T_1 = 310 \text{ K} \) \( k \) is obtained by interpolation.

\[(k - 1.400)/(1.398 - 1.400) = (310 - 300)/(350 - 300)\]

\[k = 1.3996 \]

From Table A-17, for \( T_1 = 310 \text{ K} \), \( h_1 = 310.24 \text{ kJ/kg} \),
Process 1-2s is isentropic process,
Hence, $T_1 p_1^{(1-k)/k} = T_2 p_2^{(1-k)/k}$
Hence, $T_2 = T_1 [p_1/p_2]^{(1-k)/k} = 310K [1/8]_{1.3996/1.3996}$
Hence, $T_2 = 561.31 K$
Hence, $T_{avg} = (T_1 + T_2)/2 = (310 + 561.31)/2 = 435.66 K$
From Table A-2b, for $T_{avg} = 435.66 K$, $k$ is obtained by interpolation.
$k \approx 1.395$)
\( (k-1.395)/(1.391-1.395) = (435.66 -400)/(450-400) \)
$k = 1.3921$
Hence, $T_2 = T_1 [p_1/p_2]^{(1-k)/k} = 310K [1/8]_{1.3921/1.3921}$
Hence, $T_2 = 566.86 K$
From Table A-17, for $T_2 = 561.31 K$, $h_2$ is evaluated by interpolation,
\( (h_2 - 565.17)/( 575.59 - 565.17) = (566.86 - 560)/( 570- 560) \), Hence, $h_2 = 572.32 kJ/kg$.

\[ \eta_c = \frac{h_2 - h_1}{h_2 - h_1} \]

Hence,
\[ h_2 = h_1 + \frac{h_2 - h_1}{\eta_c} \]
$h_2 = 310.24 kJ/kg + [(572.32 kJ/kg - 310.24 kJ/kg)/0.75]$
Hence, $h_2 = 659.68 kJ/kg$

$T_3 = 1160 K.$
From Table A-17, for $T_3 = 1160 K$, $h_3 = 1230.92 kJ/kg,$

Process 3-4s is isentropic process,
From Table A-2b, for $T_3 = 1160K$, $k \approx 1.336$.
Hence, $T_3 p_3^{(1-k)/k} = T_4 p_4^{(1-k)/k}$
Hence, $T_4 = T_3 [p_3/p_4]^{(1-k)/k} = 1160K [8/1]_{1.336/1.336}$
Hence, $T_4 = 687.6 K$
Hence, $T_{avg} = (1160+687.6)/2 K= 923.8 K$
From Table A-2b, for $T_{avg} = 923.8 K$, $k$ is obtained by interpolation.
$k \approx 1.344$)
\( (k-1.344)/(1.336-1.344) = (923.8-900)/(1000-900) \)
$k = 1.342$
Hence, $T_4 = T_3 [p_3/p_4]^{(1-k)/k} = 1160K [8/1]_{1.342/1.342}$
Hence, $T_4 = 682.75 K$
From Table A-17, for $T_4 = 682.75 K$, $h_4$ is evaluated by interpolation,
\( (h_4 - 691.82)/( 702.52 - 691.82) = (682.75 - 680)/( 690- 680) \), Hence, $h_4 = 694.76 kJ/kg$.

\[ \eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}} \]

Hence,
\[ h_4 = h_3 - \eta_T (h_3 - h_{4s}) \]
\[ h_4 = 1230.92 \text{ kJ/kg} - [0.82 \times (1230.92 \text{ kJ/kg} - 694.76 \text{ kJ/kg})] \]

Hence, \( h_4 = 791.27 \text{ kJ/kg} \)

Hence, from Table A-17, for \( h_4 = 791.27 \text{ kJ/kg} \), \( T_4 \) is evaluated by interpolation,

\[ (T_4 - 760)/(780 - 760) = (791.27 - 778.18)/(800.03 - 778.18), \]

Hence, \( T_4 = 771.98 \text{ K} \)

b) Evaluation of net work output

\[ q_{in} = h_3 - h_2 = 1230.92 \text{ kJ/kg} - 659.68 \text{ kJ/kg} = 571.24 \text{ kJ/kg} \]

\[ q_{out} = h_4 - h_1 = 791.27 \text{ kJ/kg} - 310.24 \text{ kJ/kg} = 481.03 \text{ kJ/kg} \]

\[ w_{net,out} = q_{in} - q_{out} = 571.24 \text{ kJ/kg} - 481.03 \text{ kJ/kg} = 90.21 \text{ kJ/kg} \]

\[ \eta_{th} = \frac{w_{net,out}}{q_{in}} = \frac{90.21 \text{ kJ/kg}}{571.24 \text{ kJ/kg}} = 0.15792 \times 100\% = 15.792\% \]

9–75 Repeat Problem 9–73 using constant specific heats at room temperature.
Air is used as the working fluid in a simple ideal Brayton cycle that has a pressure ratio of 12, a compressor inlet temperature of 300 K, and a turbine inlet temperature of 1000 K. Determine the required mass flow rate of air for a net power output of 70 MW, assuming both the compressor and the turbine have an isentropic efficiency of (a) 100 percent and (b) 85 percent. Assume constant specific heats at room temperature. **Answers:** (a) 352 kg/s, (b) 1037 kg/s
A stationary gas-turbine power plant operates on a simple ideal Brayton cycle with air as the working fluid. The air enters the compressor at 95 kPa and 290 K and the turbine at 760 kPa and 1100 K. Heat is transferred to air at a rate of 35,000 kJ/s. Determine the power delivered by this plant (a) assuming constant specific heats at room temperature and (b) accounting for the variation of specific heats with temperature.
From Table A-17, for $T_1 = 290$ K, $h_1 = 290.16 \text{ kJ/kg}$.
From Table A-2b, for $T_1 = 290$ K, $k$ is obtained by interpolation.

\[
\frac{k-1.401}{1.400-1.401} = \frac{290-250}{300-250}
\]

Hence, $k = 1.4002$

**1-2 is isentropic process.**

Hence, $T_1 p_1^{(1-k)/k} = T_2 p_2^{(1-k)/k}$
Hence, $T_2 = T_1 \left[ p_1/p_2 \right]^{(1-k)/k} = 290 \text{ K} \left[ 1/8 \right]^{(1-1.4002)/1.4002}$
Hence, $T_2 = 525.3$ K
Hence, $T_{avg} = (T_1 + T_2)/2 = (290 + 525.3)/2 = 407.65$ K
From Table A-2b, for $T_{avg} = 407.65$ K, $k$ is obtained by interpolation.

\[
\frac{k-1.395}{1.391-1.395} = \frac{407.65-400}{450-400}
\]

$k = 1.3944$

Hence, $T_2 = T_1 \left[ p_1/p_2 \right]^{(1-k)/k} = 290 \text{ K} \left[ 1/8 \right]^{(1-1.3944)/1.3944}$
Hence, $T_2 = 522.195$ K
From Table A-17, for $T_2 = 522.195$ K, $h_2$ is evaluated by interpolation.

\[
\frac{h_2-523.63}{533.98-523.63} = \frac{522.195-520}{530-520}
\]

Hence, $h_2 = 525.91 \text{ kJ/kg}$

From Table A-17, for $T_3 = 1100$ K, $h_3 = 1161.07 \text{ kJ/kg}$,

**3-4 is isentropic process.**

From Table A-2b, for $T_3 = 1100$ K, $k \equiv 1.336$.

Hence, $T_3 p_3^{(1-k)/k} = T_4 p_4^{(1-k)/k}$
Hence, $T_4 = T_3 \left[ p_3/p_4 \right]^{(1-k)/k} = 1100 \text{ K} \left[ 8/1 \right]^{(1-1.336)/1.336}$
Hence, $T_4 = 652$ K
Hence, $T_{avg} = (T_3 + T_4)/2 = (1100 + 652)/2 = 876$ K
From Table A-2b, for $T_{avg} = 876$ K, $k$ is obtained by interpolation.

\[
\frac{k-1.354}{1.344-1.354} = \frac{876-800}{900-800}
\]

Solution
Air enters the compressor of a gas-turbine engine at 300 K and 100 kPa, where it is compressed to 700 kPa and 580 K. Heat is transferred to air in the amount of 950 kJ/kg before it enters the turbine. For a turbine efficiency of 86 percent, determine (a) the fraction of the turbine work output used to drive the compressor and (b) the thermal efficiency. Assume variable specific heats for air.

Solution  An actual gas-turbine power plant operates at specified conditions. The fraction of the turbine work output used to drive the compressor and the thermal efficiency are to be determined.

Assumptions 1 Steady operating conditions exist. 2 The air-standard assumptions are applicable. 3 Kinetic and potential energy changes are negligible. 4 Air is an ideal gas with variable specific heats.

Properties The properties of air are given in Table A-17.

Analysis (a) Using the isentropic relations.

\[
T_1 = 300 \text{ K} \quad \Rightarrow \quad h_1 = 300.19 \text{ kJ/kg}
\]

\[
T_2 = 580 \text{ K} \quad \Rightarrow \quad h_2 = 586.04 \text{ kJ/kg}
\]

Hence, \( p_2 / p_1 = p_3 / p_4 = 700 \text{ kPa}/100 \text{ kPa} = 7 \)

But, \( q_{in} = h_3 - h_2 \)

Hence, \( h_3 = q_{in} + h_2 = 950 \text{ kJ/kg} + 586.04 \text{ kJ/kg} = 1536.04 \text{ kJ/kg} \)

From Table A-17, for \( h_3 = 1536.04 \text{ kJ/kg} \), \( T_3 \) is obtained by interpolation.

\[
(T_3-1400)/(1420-1400) = (1536.04 \text{ kJ/kg} - 1515.42 \text{ kJ/kg})/(1539.44 \text{ kJ/kg} - 1515.42 \text{ kJ/kg})
\]

\[
h_3 = 1536.04 \text{ kJ/kg}
\]

\[
h_4 = 653.72 \text{ kJ/kg}
\]

\[
\eta_{th} = 1 - \frac{q_{out}}{q_{in}} = 1 - \frac{h_4 - h_1}{h_3 - h_2} = 1 - \frac{653.72 - 290.16}{1161.07 - 525.91}
\]

i.e. \( \eta_{th} = 0.428 \times 100\% = 42.8\% \)

\[
\dot{W}_{net, out} = \eta_{th} \cdot \dot{Q}_{in} = 0.428 \times 35,000 \text{ kW} = 14980 \text{ kW}
\]
Hence, \( T_3 = 1420.62 \text{ K} \).
Hence, \( T_3 p_3^{(1-k)/k} = T_4 p_4^{(1-k)/k} \)
For, \( T_3 = 1420.62 \text{ K}, k = 1.336 \)
Hence, \( T_{4s} = T_3 \left[ p_3/p_4 \right]^{(1-k)/k} = 1420.62 \text{ K} [7/1]^{(1-1.336)/1.336} \)
Hence, \( T_{4s} = 870.84 \text{ K} \)
Hence, \( T_{avg} = (T_3 + T_{4s})/2 = (1420.62 + 870.84)/2 = 1145.73 \text{ K} \)
From Table A-2b, for \( T_{avg} = 1145.73 \text{ K}, k \approx 1.336 \) (same \( k \)).
Hence, From Table A-17, for \( T_{4s} = 870.84 \text{ K}, h_{4s} \) is evaluated by interpolation,
\[
(h_{4s} - 888.27 \text{ kJ/kg})/(910.56 \text{ kJ/kg} - 888.27 \text{ kJ/kg}) = (870.84 \text{ K} - 860 \text{ K})/(880 \text{ K} - 860 \text{ K})
\]
Hence, \( h_{4s} = 900.35 \text{ kJ/kg} \)
\( w_{c,in} = h_2 - h_1 = 586.04 \text{ kJ/kg} - 300.19 \text{ kJ/kg} = 285.85 \text{ kJ/kg} \)
\( w_{T,out} = \eta_T \cdot w_{T,out,is} = \eta_T \cdot (h_3 - h_{4s}) = (0.86)(1536.04 \text{ kJ/kg} - 900.35 \text{ kJ/kg}) = 546.7 \text{ kJ/kg} \)
Thus, \( r_{bw} = w_{c,in} / w_{T,out} = 285.85 \text{ kJ/kg} / 546.7 \text{ kJ/kg} = 0.52287 \times 100\% = 52.29\% \).
(b) \( w_{net,out} = w_{T,out} - w_{c,in} = (546.7 \text{ kJ/kg} - 285.85 \text{ kJ/kg}) = 260.84 \text{ kJ/kg} \)
Thus, \( \eta_{in} = w_{net,out} / q_{in} = 260.84 \text{ kJ/kg} / 950 \text{ kJ/kg} = 0.2746 \times 100\% = 27.46\% \)

9–79 Repeat Problem 9–78 using constant specific heats at room temperature.
A gas-turbine power plant operates at specified conditions. The fraction of the turbine work output used to drive the compressor and the thermal efficiency are to be determined.

Assumptions 1 Steady operating conditions exist. 2 The air-standard assumptions are applicable. 3 Kinetic and potential energy changes are negligible. 4 Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are \( c_p = 1005 \text{ kJ/kg} \cdot \text{K} \) and \( k = 1.4 \) (Table A-2).

Analysis (a) Using constant specific heats.

\[
\begin{align*}
r_p &= \frac{P_2}{P_1} = \frac{700}{100} = 7 \\
q_{in} &= h_3 - h_2 = c_p (T_3 - T_2) \\
T_3 &= T_2 + \frac{q_{in}}{c_p} \\
&= 580 \text{ K} + (950 \text{ kJ/kg})/(1005 \text{ kJ/kg} \cdot \text{K}) \\
&= 1525.3 \text{ K} \\
T_{4s} &= T_3 \left( \frac{P_4}{P_3} \right)^{(k-1)/k} = (1525.3 \text{ K}) \left( \frac{1}{1.4} \right)^{0.4/1.4} = 874.8 \text{ K} \\
w_{C,in} &= h_2 - h_1 = c_p (T_2 - T_1) = (1005 \text{ kJ/kg} \cdot \text{K}) [580 - 300] \text{K} = 281.4 \text{ kJ/kg} \\
w_{T,out} &= \eta_T (h_3 - h_{4s}) = \eta_T c_p (T_3 - T_{4s}) = (0.86)(1005 \text{ kJ/kg} \cdot \text{K})(1525.3 - 874.8) \text{K} = 562.2 \text{ kJ/kg} \\
\text{Thus, } \quad r_{net} = \frac{w_{C,in}}{w_{T,out}} = \frac{281.4 \text{ kJ/kg}}{562.2 \text{ kJ/kg}} = 50.1\% \\
\text{(b) } \quad w_{net,out} = w_{T,out} - w_{C,in} = 562.2 - 281.4 = 280.8 \text{ kJ/kg} \\
\eta_{in} &= \frac{w_{net,out}}{q_{in}} = \frac{280.8 \text{ kJ/kg}}{950 \text{ kJ/kg}} = 29.6\%
\end{align*}
\]

9–82 A gas-turbine power plant operates on the simple Brayton cycle with air as the working fluid and delivers 32 MW of power. The minimum and maximum temperatures in the cycle are 310 and 900 K, and the pressure of air at the compressor exit is 8 times the value at the compressor inlet. Assuming an isentropic efficiency of 80 percent for the compressor and 86 percent for the turbine, determine the mass flow rate of air through the cycle. Account for the variation of specific heats with temperature.

Solution A 32-MW gas-turbine power plant operates on a simple Brayton cycle with air as the working fluid. The mass flow rate of air through the cycle is to be determined.

Assumptions 1 Steady operating conditions exist. 2 The air-standard assumptions are applicable. 3 Kinetic and potential energy changes are negligible. 4 Air is an ideal gas with variable specific heats.

Properties The properties of air are given in Table A-17.

Analysis Using variable specific heats.
For $T_1 = 310$ K, $h_1 = 310.24$ kJ/kg

From Table A-2b, for $T = 310$ K, $k$ is evaluated by interpolation,

\[
\frac{(k - 1.400)}{(1.398 - 1.400)} = \frac{(310 - 300)}{(350 - 300)}
\]

Hence, $k = 1.3996$

$p_2 / p_1 = 8$

Process 1-2s is isentropic compression,

Hence, $T_{2s} = T_1 \left(\frac{p_1}{p_2}\right)^{(k-1)/k}

Hence, $T_{2s} = 310 K \left[\frac{1}{8}\right]^{1-1.3996} = 310 K \left[\frac{1}{8}\right]^{1-1.3996} / 1.3996$

Hence, $T_{2s} = 561.31 K$

From Table A-2b, For $T_{avg} = (310 K + 561.31 K) / 2 = 435.65$ K, $k$ is evaluated by interpolation,

\[
\frac{(k - 1.395)}{(1.391 - 1.395)} = \frac{(435.65 - 400)}{(450 - 400)}
\]

Hence, $k = 1.39215$

Hence, $T_{2s} = T_1 \left(\frac{p_1}{p_2}\right)^{(k-1)/k} = 310 K \left[\frac{1}{8}\right]^{1-1.39215} / 1.39215$

Hence, $T_{2s} = 556.864 K$

From Table A-17, for $T_{2s} = 556.864 K$, $h_{2s}$ is evaluated by interpolation,

\[
\frac{(h_{2s} - 555.74 kJ/kg)}{(565.17 kJ/kg - 555.74 kJ/kg)} = \frac{(556.864 - 550 K)}{(560 K - 550 K)}
\]

Hence, $h_{2s} = 556.864 kJ/kg$.

For $T_3 = 900$ K, $k = 1.344$ kJ/kg, $h_3 = 932.93$ kJ/kg

Process 3-4s is isentropic compression,

Hence, $T_{4s} = T_3 \left(\frac{p_3}{p_4}\right)^{(k-1)/k}

Hence, $T_{4s} = T_3 \left[\frac{p_3}{p_4}\right]^{(k-1)/k} = 900 K \left[\frac{8}{1.344}\right]^{1-1.344} / 1.344$

Hence, $T_{4s} = 528.56 K$

From Table A-2b, For $T_{avg} = (900 K + 528.56 K) / 2 = 714.28$ K, $k$ is evaluated by interpolation,

\[
\frac{(k - 1.364)}{(1.359 - 1.364)} = \frac{(714.28 - 700)}{(750 - 700)}
\]

Hence, $k = 1.3626$

Hence, $T_{4s} = T_3 \left[\frac{p_3}{p_4}\right]^{(k-1)/k} = 900 K \left[\frac{8}{1.3626}\right]^{1-1.3626} / 1.3626$

Hence, $T_{4s} = 517.514 K$

From Table A-17, for $T_{4s} = 517.514 K$, $h_{4s}$ is evaluated by interpolation,

\[
\frac{(h_{4s} - 513.32 kJ/kg)}{(523.63 kJ/kg - 513.32 kJ/kg)} = \frac{(517.514 - 510 K)}{(520 K - 510 K)}
\]
Hence, \( h_{4s} = 521.07 \text{ kJ/kg} \).

Hence, \( w_{c,is} = h_{2s} - h_1 = 556.864 \text{ kJ/kg} - 310.24 \text{ kJ/kg} = 246.624 \text{ kJ/kg} \).

Similarly, \( w_{T,is} = h_3 - h_{4s} = 932.93 \text{ kJ/kg} - 521.07 \text{ kJ/kg} = 411.86 \text{ kJ/kg} \).

Hence, \( w_{c,a} = w_{c,is} / \eta_c = 246.624 \text{ kJ/kg} / 0.8 = 308.28 \text{ kJ/kg} \).

Similarly, \( w_{T,a} = \eta_T * w_{T,is} = 0.86 * 411.86 \text{ kJ/kg} = 354.86 \text{ kJ/kg} \).

Hence, \( w_{\text{net,out}} = w_{T,a} - w_{c,a} = 354.86 \text{ kJ/kg} - 308.28 \text{ kJ/kg} = 45.92 \text{ kJ/kg} \).

Hence, \( \dot{m} = \frac{w_{\text{net,out}}}{w_{\text{net,out}}} = \frac{32 \times 10^6}{45.92 \times 10^3} = 696.87 \text{ kg/s} \)

9–83 Repeat Problem 9–82 using constant specific heats at room temperature.

**Solution**

A 32-MW gas-turbine power plant operates on a simple Brayton cycle with air as the working fluid. The mass flow rate of air through the cycle is to be determined.

**Assumptions**
1. Steady operating conditions exist.
2. The air-standard assumptions are applicable.
3. Kinetic and potential energy changes are negligible.
4. Air is an ideal gas with constant specific heats.

**Properties**
The properties of air at room temperature are \( c_p = 1.005 \text{ kJ/kg·K} \) and \( k = 1.4 \) (Table A-2).

**Analysis**
Using constant specific heats,

\[
T_{2s} = T_1 \left( \frac{P_1}{P_2} \right)^{(k-1)/k} = (310 \text{ K})(8)^{0.414} = 201.5 \text{ K}
\]

\[
T_{4s} = T_3 \left( P_3 \right)^{(k-1)/k} = (310 \text{ K})(1)^{0.414} = 490.8 \text{ K}
\]

\[
w_{\text{net,out}} = w_{T,a} - w_{c,a} = \eta_T c_p (T_3 - T_{4s}) - c_p (T_2s - T_1) / \eta_c
\]

\[
= (1.005 \text{ kJ/kg·K})(0.86)(900 - 496.8) - (561.5 - 310)(0.80)K
\]

\[
- 32.5 \text{ kJ/kg}
\]

And

\[
\dot{m} = \frac{w_{\text{net,out}}}{w_{\text{net,out}}} = \frac{32 \times 10^6}{32.5 \text{ kJ/kg}} = 984.6 \text{ kg/s}
\]

9–85C How does regeneration affect the efficiency of a Brayton cycle, and how does it accomplish it?

**Solution**
Regeneration increases the thermal efficiency of a Brayton cycle by capturing some of the waste heat from the exhaust gases and preheating the air before it enters the combustion chamber.

9–87C Define the effectiveness of a regenerator used in gas-turbine cycles.
An ideal Brayton cycle with regeneration has a pressure ratio of 10. Air enters the compressor at 300 K and the turbine at 1200 K. If the effectiveness of the regenerator is 100 percent, determine the net work output and the thermal efficiency of the cycle. Account for the variation of specific heats with temperature.

\( h_1 = 300.19 \text{ kJ/kg} \)

Process 1-2 is isentropic compression,
Hence, \( T_2 = T_1 \left( \frac{p_1}{p_2} \right)^{(1-k)/k} \)
Hence, \( T_2 = T_1 \left[ \frac{p_1}{p_2} \right]^{(1-k)/k} = 300 \text{ K} \left[ \frac{1}{10} \right]^{(1-1.4)/1.4} \)
Hence, \( T_2 = 579.2 \text{ K} \)
From Table A-17, for \( T = 579.2 \text{ K} \), \( h_2 \approx 586 \text{ kJ/kg} \)
Hence, \( w_{c,in} = h_2 - h_1 = 586 \text{ kJ/kg} - 300.19 \text{ kJ/kg} = 285.81 \text{ kJ/kg}. \)

\( T_3 = 1200 \text{ K} \), Hence, \( h_3 = 1277.79 \text{ kJ/kg} \)

Process 3-4 is isentropic expansion,
Hence, \( T_4 = T_3 \left( \frac{p_3}{p_4} \right)^{(1-k)/k} \)
Hence, \( T_4 = T_3 \left[ \frac{p_3}{p_4} \right]^{(1-k)/k} = 1200 \text{ K} \left[ 10 \right]^{(1-1.4)/1.4} \)
Hence, \( T_4 = 673.33 \text{ K} \)
From Table A-17, for \( T = 673.33 \text{ K} \), \( h_4 \) is evaluated by interpolation,
\( (h_4 - 681.14 \text{ kJ/kg})/(691.82 \text{ kJ/kg} - 681.14 \text{ kJ/kg}) = (673.33 \text{ K} - 670 \text{ K})/(680 \text{ K} - 670 \text{ K}) \)

Hence, \( h_4 = 684.7 \text{ kJ/kg} \).

Hence, \( w_{T,\text{out}} = h_3 - h_4 = 1277.79 \text{ kJ/kg} - 684.7 \text{ kJ/kg} = 593.1 \text{ kJ/kg} \).

\( w_{\text{net}} = w_{T,\text{out}} - w_{\text{c,in}} = 593.1 \text{ kJ/kg} - 285.81 \text{ kJ/kg} = 307.3 \text{ kJ/kg} \).

As \( \varepsilon = 100\% \), \( h_5 = h_4 = 684.7 \text{ kJ/kg} \).

\( q_{\text{in}} = h_3 - h_5 = 1277.79 \text{ kJ/kg} - 684.7 \text{ kJ/kg} = 593.1 \text{ kJ/kg} \).

Hence, \( \eta_{\text{th}} = w_{\text{net}} / q_{\text{in}} = 307.3 \text{ kJ/kg} / 593.1 \text{ kJ/kg} = 0.5181 \times 100\% = 51.81\% \).
